## Morphological, physiological and biochemical aspects of halophyte *Petrosimonia triandra* grown in natural habitat

### Abstract

Salt tolerance mechanisms of halophyte *Petrosimonia triandra*, growing in its natural habitat in Cojocna commune, Cluj county, Romania, were investigated by analysis of biomass, growth parameters, water status, ion content, photosynthetic and antioxidative system efficiency, proline accumulation and lipid degradation. Two sampling sites with different soil electrical conductivities (EC) were selected, site 1: 3.14 dS m<sup>-1</sup> and site 2: 4.45 dS m<sup>-1</sup>. Higher salinity proved to have a positive effect on growth, the relative water content did not decline severely, the Na<sup>+</sup> and K<sup>+</sup> content of the roots, stem and leaves was larger, the function of photosynthetic apparatus and photosynthetic pigment content were not altered. The efficiency of antioxidative defence system was found to be assured by coordination of several reactive oxygen species scavengers. The presence of higher salinity, lead to accumulation of the osmolyte proline, while degradation of membrane lipids was reduced. As a whole, *P. triandra* evolved different adaptational strategies to counteract soil salinity, which includes morphological and physiological adaptations, preservation of photosynthetic activity, development of an efficient antioxidative system and accumulation of the osmotic compound, proline.

**Keywords:** *Petrosimonia triandra*, salinity, biomass, photosynthetic pigments, antioxidant, proline.

### Introduction

Salinity is one of the most important abiotic stress factor reducing crop productivity and quality worldwide (Yamaguchi and Blumwald 2005; Okorogbona et al. 2015). Approximately 20% of the world's cultivated and 33% of the irrigated land is affected by high levels of soil salinity, limiting plant growth and survival. Furthermore, salinized area increases yearly with 10% due to low precipitation, irrigation with saline water and poor agricultural practices. It is estimated that by 2050, 50% of the arable land would be salinized (Jamil et al. 2011; Shrivastava and Kumar 2015). Sodium (Na<sup>+</sup>) and chloride (Cl<sup>-</sup>) ions constitute the major ionic components of soils and seawater, but other ions, such as sulphate (SO<sub>4</sub><sup>2-</sup>) and calcium (Ca<sup>2+</sup>) play a role in salinity formation.

Uptake and overaccumulation of Na ions induce salt stress in many plant species disturbing normal growth and development. Concentrations of 150 - 400 mM NaCl in soil can affect the volume of intercellular spaces in leaves, the thickness of the whole leaf and of the palisade parenchyma and the size of the epidermal and spongy parenchyma cells (Molassiotis et al. 2006; Milic et al. 2013; Montero et al. 2018). Photosynthesis is negatively affected, because damaging

1 concentrations of Na<sup>+</sup> and / or Cl<sup>-</sup> can accumulate in chloroplasts (Boyer 1976; Sudhir and Murthy 2004). Photosynthetic  
2 electron transport is relatively insensitive to salt, but the carbon metabolism or photophosphorylation is affected (Sudhir  
3 and Murthy 2004). The lipid and protein composition of plasma membranes are severely modified by salt accumulation  
4 leading to ion imbalance and hyperosmotic stress (Hayashi and Murata 1998; Parida and Das 2005). Osmotic effect happens  
5 when dissolved solutes near the plant root zone generate a low osmotic potential that decreases the soil water potential,  
6 which negatively affects the water balance of the plant. Under normal conditions, the cytosol of the plant cells contains  
7 to 10 mM Na<sup>+</sup> and 100 to 200 mM K<sup>+</sup> (Binzel et al. 1988; Blumwald et al. 2000), that allow the enzymes to function  
8 optimally. A high ratio of Na<sup>+</sup> / K<sup>+</sup> and high concentrations of total salt inactivate enzymes and inhibit protein synthesis  
9 (Blumwald et al. 2000). Osmotic stress induced by high salinity is typically accompanied by oxidative stress caused by the  
10 accumulation of reactive oxygen species (ROS) and consequently, an increase in ROS scavenging enzymes: superoxide  
11 dismutase (SOD), catalase (CAT), ascorbate peroxidase (APX), glutathione reductase (Parida et al. 2004; Yildiztugay et  
12 al. 2014; Kibria et al. 2017).

13  
14 Halophyte species are considered extremophile plants for they are able to tolerate and complete their life cycle  
15 under a large scale of soil salinity. Halophytes present a series of anatomical and physiological adaptation mechanisms  
16 allowing them to counter the ion toxicity and water failure. Some halophytes are able to exclude salt from shoot meristems  
17 and leaves as they have developed salt glands on the surface of the leaves (*Atriplex* sp.) or accumulate Na<sup>+</sup> and Cl<sup>-</sup> ions in  
18 the vacuole to avoid cytotoxicity (Taiz and Zeiger 1998). Halophytes, such as *Suaeda maritima* (Flowers 1972; Flowers  
19 and Colmer 2015) and *Atriplex nummularia* (de Araújo et al. 2006) show growth stimulation up to 300 mM Cl<sup>-</sup> levels,  
20 while *Salicornia europaea*, *Atriplex leucoclada* and *Kochia scoparia* show greater growth under increasing salt  
21 concentrations up to 500 mM NaCl (Mohammadi and Kardan 2015). Some halophytes are able to scavenge cell detrimental  
22 ROS, by a series of osmolytes that ensure protection of the subcellular structures. Halophytes usually accumulate one  
23 dominant osmolyte, like proline, glycine betaine, sorbitol, β-alanine betaine, choline-*O*-sulphate or sugar (Tipirdamaz et  
24 al. 2006; Arbona et al. 2010; Lugan et al. 2010; Slama et al. 2015), but some halophytes accumulate more than one  
25 compatible solute (Gagneul et al. 2007).

26  
27 *Petrosimonia* species, members of Chenopodiaceae family, are typical halophytes native to South East of Europe  
28 (Edmondson 1993; Grigore et al. 2012; Todorova et al. 2014) and regionally in Asia (Breckle et al. 2011; Zörb et al. 2013).  
29 All *Petrosimonia* species identified are living in saline soils with 2 - 28 dS m<sup>-1</sup> EC (Grigore et al. 2012; Zörb et al. 2013;  
30 Todorova et al. 2014), reaching up to 0.5 m height in arid areas. Although very little information is published about this  
31 species, it has been proposed as an antioxidant source for the expanding food crisis (Grigore and Oprica 2015). *P. triandra*  
32 also represents an interesting species with Kranz anatomy pattern in its stem, making it an attractive tool for plant  
33

1 anatomical studies, since it is the only Romanian *Petrosimonia* species with this specificity (Grigore et al. 2012). Because  
2 of its salty taste, *P. triandra* is often consumed, by local people, in salads. Like other halophytes, based on its salt  
3 accumulation capacity, it could also be used as a biodesalinating plant, for the purpose of expanding the arable lands and  
4 generate pastures. Halophyte crop production represents a major trend in the development and use of territories hardly  
5 suitable for agriculture due to the shortage or full absence of freshwater. Halophytes are an alternative source of feeds,  
6 grains, grass forage, and medicinal raw materials, as well as a means of reconstructing the plant cover and improve the  
7 biological productivity of degraded pasture lands (Shamsutdinov et al. 2017). The ecological importance consists in the  
8 non-monetary value of the presence of halophytic vegetation, which has a protective role against soil erosion, ensures the  
9 habitat of some animal species, and represents an insular living environment in the Transylvanian Plain.

10  
11  
12 In the current study, we aimed to investigate the adaptation mechanisms of *P. triandra* to salt stress by comparing  
13 morphological, physiological and biochemical parameters of plants grown in their natural habitat, in soils with different  
14 salinities in Cojocna commune, Cluj County, Romania. Characterization of *P. triandra* contributes to the understanding of  
15 salinity tolerance mechanism of halophytes and can provide a substantial advantage for the extension of arable land for  
16 crop species in Europe and especially in the Carpathian Basin.

### 32 33 **Plant material sampling site**

34  
35  
36 Cojocna commune from Cluj County, Romania (fig. 1A), is located in Fizeş Plain, covers an area of 238 km<sup>2</sup>, with a  
37 population of 4400 inhabitants. The wide and flat meadow, marked by crust and saline efflorescences, from the eastern  
38 edge of the Cojocna commune, outlines an important massive salt in the basement. On the surface occupied by medium-  
39 sized Miocene deposits, erosion created wide valleys, accompanied by numerous salt springs, sapropelic mud plateaus,  
40 salty and halophyte vegetation. The climate is temperate-continental, characterized by warm summers and cold winters.  
41 The average annual temperature is 9.6 °C with a multiannual minimum of -15 °C and a maximum of +30 °C in July /  
42 August. Annual average rainfall is 886 mm.

43  
44  
45  
46 Two sampling sites from Cojocna (Cluj County, Romania, coordinates for 3.14 dS m<sup>-1</sup> soil electrical conductivity:  
47 N46.74319 E23.84290 – site 1, and for 4.45 dS m<sup>-1</sup> soil electrical conductivity: N46.74328 E23.84295 – site 2) were marked  
48 and used for analysis of *Petrosimonia triandra* (Pall.) Simonk. plants growing there in the summer of 2016 (fig. 1B). The  
49 3.14 dS m<sup>-1</sup> and 4.45 dS m<sup>-1</sup> values correspond to a moderate saline soil (Marcar and Crawford, 2004). The sampling sites  
50 were chosen deliberately to represent different soil salinity levels. The analyzed area and plant species were chosen based

4

#### 5 **Determination of morphological and growth parameters**

6

7 At each sampling site 10 plants were chosen for the analysis of morphological and growth parameters. The plants were  
8 carefully dug out to maintain their root intact. Length measurements were done using a millimetre ruler. Primary root  
9 length was measured from the base of the root to its deeper point, shoot length was measured from the base of the shoot to  
10 its highest point. For leaf area measurements, the leaves were excised, placed onto millimetre paper and photographed.  
11 ImageJ program was used to quantify the leaf area of the photographed leaves. Analytical scale (G&G, Electronic scale  
12 JJ200B) was used to measure the fresh weight of the leaves, stems, and roots right after digging out the plants and  
13 immediately after the excision of the plant organs. The samples were carried into the laboratory, oven dried in paper bags  
14 at 70°C for 48 h, and then the dry weight of leaves, stems and roots were measured. The ratio of root and shoot (stem+leaf)  
15 fresh (FW) and dry (DW) weights were calculated.

#### 26 **Measurement of water relations**

27

28 For turgid weight measurement, the leaf fresh weight (LFW) was recorded immediately after field sampling, then, the  
29 leaves were immersed into distilled water and kept at room temperature. After 24 h of soaking, the leaves were water dried  
30 by blotting onto filter paper and leaf turgid weight (LTW) was recorded. Leaf dry weight (LDW) was measured upon  
31 incubation at 70°C for 48h. Relative water content was calculated as follows:  $RWC\% = (LFW - LDW / LTW - LDW) \times$

#### 60 **Determination of plant ion content**

61

62 The ion-chromatographic analysis was performed at room temperature ( $21 \pm 2^\circ\text{C}$ ) using Dionex ICS-1500 system equipped  
63 with a temperature compensated conductivity cell (Cataldi et al. 2003). The ion separation was carried out with two  
64 different ion-exchange columns: one for cations ( $\text{Na}^+$ ,  $\text{NH}_4^+$ ,  $\text{K}^+$ ,  $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ ), another for anions ( $\text{F}^-$ ,  $\text{Cl}^-$ ,  $\text{NO}_2^-$ ,  $\text{Br}^-$ ,  $\text{NO}_3^-$ ,  
65  $\text{PO}_4^{3-}$ ,  $\text{SO}_4^{2-}$ ). Upon harvest, the plant samples were rinsed three times in distilled water, blotted on filter paper (Cataldi et  
al. 2003), and then the roots were separated from the stems. After separation, the samples were quickly frozen in liquid  
nitrogen, then ground into powder and stored in airtight vials at room temperature. In order to determine the content of  
anions and cations, the obtained tissue powder (100 mg) was mixed with ultra-pure water (15 ml), the suspension was  
shacked for 15 min to facilitate contact between the plant tissue and extracting solvent (ultrapure water) and then

1 centrifuged at 14000 rpm for 15 min (centrifuge type: Sigma, rotor 12124 PP 399/F). The samples were filtered through  
2 single-use MCE 0.45  $\mu\text{m}$  filters to remove any particulate matter and analysed with ion-chromatograph.  
3

4 In order to determine the NaCl content of the soil samples, we considered the concentration of  $\text{Na}^+$ . The NaCl  
5 content of the soil were calculated from the measured IC (Ion Chromatography values) and was converted to  $\text{mM L}^{-1}$  using  
6 the molecular weight (atomic mass) data. Thus, the soil NaCl in the first sampling site ( $\text{EC}=3.14 \text{ dS m}^{-1}$ ) was  $24.35 \text{ mM}$   
7  $\text{L}^{-1}$  while in the second site ( $\text{EC}= 4.45 \text{ dS m}^{-1}$ )  $41.35 \text{ mM L}^{-1}$ , respectively. Therefore, the difference in NaCl content  
8 between the two sampling sites is 70%.

13

### 14 **Determination of photosystem II efficiency and of photosynthetic pigment content**

15  
16 Quantum yield, a measure of the photosystem II efficiency (PSII) equivalent, in light adapted leaves, to  $\text{Fv}'/\text{Fm}'$  was  
17 determined by a portable FluorPen FP100 (Ptushenko et al. 2014). Leaves were light adapted, the PAR (photosynthetic  
18 active radiation) value was  $1700\text{-}1800 \text{ mmol m}^{-2} \text{ s}^{-1}$ . Chlorophyll and carotenoid content were determined according to the  
19 method described by Lichtenthaler (1987). Leaves (0.1 g) were grinded, then 2 ml 100% acetone was added and kept at  
20  $4^\circ\text{C}$  for 24 h. The homogenate was centrifuged at  $15000 \text{ g}$  for 5 min, and the supernatant was treated with 80% acetone for  
21 24 h. The optical density was measured by a VWR UV-1600PC spectrophotometer at 646.8 and 663.2 nm for Chl  $a + b$   
22 determination, and 470 nm for carotenoid determination. The concentration of chlorophyll was calculated according to the  
23 equations:  $\text{Chl } a = 12.21 A_{663.2} - 2.81 A_{646.8}$ ,  $\text{Chl } b = 20.13 A_{646.8} - 5.03 A_{663.2}$  and  $\text{Chl } a + b = 7.15 A_{663.2} + 18.71 A_{646.8}$ . The  
24 concentration of carotenoids was calculated according to the equation:  $(1000 A_{470} - 3.27 \text{ Chl } a - 104 \text{ Chl } b) / 227$ .

### 37 **Quantification of reactive oxygen species detoxifying enzyme activities**

38  
39 For antioxidative enzyme assays, field collected leaves (1 g) were homogenized in a reaction mixture containing 40 mg  
40 polyvinyl pyrrolidone (PVP) and 4 ml of 0.1 M phosphate buffer (pH 7.0) with 0.1 mM EDTA. The homogenate was  
41 centrifuged and the supernatant was used for determination of different enzymes activities. Soluble protein concentration  
42 was determined by the method of Bradford (1976). The methods used to measure the activity of different enzymes  
43 (superoxide dismutase, catalase, ascorbate peroxidase, guaiacol peroxidase, glutathione transferase) were published earlier  
44 by Székely et al. (2008).  
45  
46  
47  
48  
49  
50

### 52 **Measurement of free proline content and of lipid peroxidation**

53  
54 Free proline content was measured in the field collected leaf tissues by colorimetric assay according to the method  
55 described by Bates (1973) and modified by Ábrahám et al. (2003). The end product of lipid peroxidation, malondialdehyde  
56 (MDA) was measured by thiobarbituric acid (TBA) test (Heath and Parker 1968). Field collected leaf tissues (0.1 g) were  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 homogenized in 0.5 ml of 20% w/v TCA solution. The homogenate was centrifuged at 15000 g for 5 min at 4°C, and then  
2 0.5 ml of 1% w/v TBA was added to the supernatant. The mixture was incubated at 100°C for 30 min, and then the tubes  
3  
4 were placed on ice to stop the reaction. Samples were centrifuged at 10000 g for 5 min, and the absorbance of supernatant  
5  
6 (where some shade of pink MDA-TBA complex was formed) was measured at 535 and 730 nm. The intensity of  
7  
8 the pink pigment indicates the extent of lipid peroxidation. The amount of MDA-TBA complex was calculated according  
9  
10 to the equation:  $X (\%) = 100 \times (OD_{535} - OD_{730})$ .

### 11 12 13 **Statistical analysis**

14  
15 Statistical analysis was performed using the Welch Two Sample t-test in RStudio statistical software (v1.1.423), where  
16  
17 \*p= 0.05-0.01, \*\*p = 0.01-0.001 and \*\*\*p < 0.001.

## 18 19 20 21 22 **Results**

### 23 24 25 **Effect of salinity on growth of *Petrosimonia triandra* plants**

26  
27 In order to assess morphological responses of *P. triandra* to salinity, plants grown in their natural environment in Cojocna  
28 commune, Cluj County, Romania (fig. 1). Growth parameters of *P. triandra* plants grown under two different salinities  
29  
30 were investigated. The soil EC at the two sampling sites were 3.14 and 4.45 dS m<sup>-1</sup>, corresponding to approximately 24.35  
31  
32 mM (site 1) and 41.35 mM (site 2) NaCl in soil, respectively. Despite of the higher soil salinity at site 2, *P. triandra* plants  
33  
34 grown there were more vigorous than those grown at site 1. The fresh and dry biomass of the above- and underground  
35  
36 organs of *P. triandra* plants grown in higher salinity were between 21 and 35% significantly larger than of those grown in  
37  
38 lower salinity (Table 1). While fresh weight biomass of roots, stem and leaves were by 21-30% larger, the dry biomass  
39  
40 differences were 27-35% larger in plants grown in higher salinity compared to those in site 1, with lower soil salinity (Table  
41  
42 1). The enhancement in fresh and dry biomass of leaves was 30% and 35%, the fresh and dry biomass of stems was larger  
43  
44 by 27% and 32%, while the root fresh and dry biomass increased with 21 and 33%, respectively (Table 1). Root to shoot  
45  
46 fresh or dry weight ratios displayed no statistically significant differences between the two sampling sites (Table 1). The  
47  
48 length of the primary root, although 24% larger, was not statistically significant in plants grown at 4.45 dS m<sup>-1</sup> EC of soil  
49  
50 compared to those grown at 3.14 dS m<sup>-1</sup> (Table 2). Nonetheless, plant height and total leaf area were by 29% and 69%,  
51  
52 respectively, significantly larger in plants grown in higher salinity (Table 2).  
53  
54  
55  
56

### 57 **Accumulation of mineral ions in *Petrosimonia triandra* plants grown in soils with different salinities**

58  
59  
60  
61  
62  
63  
64  
65

1  
2 The influence of salt on mineral ion distribution in different organs are presented in Table 3. The levels of Na<sup>+</sup> and K<sup>+</sup>  
3 cations were larger in roots (Na<sup>+</sup>: 51%, K<sup>+</sup>: 55%), stems (Na<sup>+</sup>: 5%, K<sup>+</sup>: 51%) and leaves (Na<sup>+</sup> and K<sup>+</sup> 30%) of plants grown  
4 at higher salinity in comparison to those grown at lower salinity. The levels of Ca<sup>2+</sup> and Mg<sup>2+</sup> exceeded in roots (Ca<sup>2+</sup>:  
5 440%, Mg<sup>2+</sup>: 354%) and stems (Ca<sup>2+</sup>: 240%, Mg<sup>2+</sup>: 58%), but decreased in leaves (Ca<sup>2+</sup>: 160%, Mg<sup>2+</sup>: 74%) of plants grown  
6 at higher soil salinity. The level of Cl<sup>-</sup> anion increased in roots (28%), stems (6%) and leaves (11%) in presence of higher  
7 EC (4.45 dS m<sup>-1</sup> μS). The Na<sup>+</sup> / K<sup>+</sup> ratio decreased in stems by 43% and remained unchanged in roots and leaves (Table  
8 3).  
9  
10  
11  
12  
13

### 14 **PSII efficiency and photosynthetic pigment content in plants grown under different soil salinity**

15  
16 The quantum yield of PSII (Fv'/Fm') of plants, showed constant values around 72% in light adapted leaves (fig. 2A) in  
17 both sites of *P. triandra* habitat. Regarding the photosynthetic pigments, only carotenoids (fig. 2C), not chlorophyll *a* and  
18 *b* (fig. 2B) displayed larger accumulation in leaves of plants grown at higher soil salinity. The accumulation of carotenoids  
19 in *P. triandra* was 37% significantly higher in leaves of plants grown in the presence of 4.45 dS m<sup>-1</sup> EC compared to those  
20 of plants living at 3.14 dS m<sup>-1</sup> EC.  
21  
22  
23  
24  
25  
26  
27

### 28 **Effect of different salinity on the oxidative defence system**

29  
30 The activity of plant enzymes important for stress tolerance: superoxide dismutase (SOD), catalase (CAT), ascorbate  
31 peroxidase (APX), guaiacol peroxidase (GPX) and glutathione transferase (GST) was investigated in leaves of field living  
32 plants. The activity of all investigated enzymes was statistically significantly increased in plants grown at higher salinity  
33 in comparison to those living at lower soil salinity (fig. 3). SOD and CAT activity levels were 50% and 60% higher,  
34 respectively (figs. 3A, B), APX and GPX activity levels were greater by 30-40% (figs. 3C, D), whereas GST activity was  
35 10% increased (fig. 3E) in the presence of elevated soil EC. These findings suggest that *P. triandra* possesses an efficient  
36 antioxidative system, which is activated by elevated salinity and is able to scavenge the harmful ROS during oxidative  
37 stress caused by high salinity.

### 48 **Effect of different salinity on proline and lipid peroxidation levels**

49  
50 The level of free proline in *P. triandra* leaves was significantly increased by 20% (fig. 4A) in the presence of higher soil  
51 salinity. To quantify the lipid degradation, as an effect of oxidative damage, we measured the level of malondialdehyde  
52 (MDA), as the end product of lipid peroxidation. MDA was used as an indicator of membrane lipid peroxidation. The level  
53 of lipid degradation was 18% significantly lower in plants grown under higher (salinity 4.45 dS m<sup>-1</sup> EC) than under lesser  
54 soil salinity (3.14 dS m<sup>-1</sup>) (fig. 4B).

## Discussion

Salinization of arable soils is of real concern for it negatively affects cultivated plants, thus posing a risk to food production. By definition, a saline soil is one in which the electrical conductivity (EC) of the saturation extract in the root zone exceeds  $4 \text{ dS m}^{-1}$  (decisiemens per meter), where  $4 \text{ dS m}^{-1}$  corresponds to approximately  $40 \text{ mM NaCl}$  or more at  $25^\circ\text{C}$  (Richards 1954; Amacher et al. 2000; Marcar and Crawford 2004; Chinnusamy et al. 2005). Halophyte species could be used in saline soils as they are able to grow and develop under such conditions. In our study, *Petrosimonia triandra*, a halophyte member of the Chenopodiaceae family, showed enhancement of growth under higher ( $4.45 \text{ dS m}^{-1}$  EC) in comparison to lower ( $3.14 \text{ dS m}^{-1}$  EC) soil salinity conditions in its natural environment. The increase in the length and surface area of the aboveground plant organs are in accordance to the increase in their biomass (Table 1), suggesting that the tolerance response of this plant species to high salt is to develop its aerial parts rather than the underground organs. This is not surprising, given that other members of the Chenopodiaceae family like *Salsola soda* can grow and tolerate even higher soil salinity (EC  $\sim 10 \text{ dS m}^{-1}$  or above) (Centofanti and Banuelos 2015; Karakas et al. 2017). Study of six halophyte species (*Suaeda maritima*, *Sesuvium portulacastrum*, *Clerodendron inerme*, *Ipomoea pes-caprae*, *Heliotropium curassavicum* and *Excoecaria agallocha*) which are able to accumulate salt, showed that *S. maritima* and *S. portulacastrum* decreased the EC of soil from 4.9 to 1.4 and  $2.5 \text{ dS m}^{-1}$ , respectively, demonstrating their potential for soil desalinization purposes (Ravindran et al. 2007). Apart from salt stress, halophytes have to be able to cope with water stress, too, for that the presence of high salts in the soil impeded water absorption. In the current study, the relative water content (RWC) of the leaves of *P. triandra* was lower only by 17% in plants grown at  $4.45 \text{ dS m}^{-1}$  EC, but remained around the value of 70%, showing that the salt stress conditions do not severely affect the plants water status (Table 2). *P. triandra* is able to maintain a high RWC ( $\sim 70\%$ ) when encounters salt stress, demonstrating that plants possess an efficient mechanism to adjust cell cytosol osmotically, and to absorb enough water from the soil.

The concentrations of  $\text{Na}^+$  and  $\text{K}^+$  in plants is an indicator of plant tolerance to salt stress.  $\text{Na}^+$  accumulation in leaves can repress photosynthetic enzymes and carbohydrate metabolism, process which induce oxidative damage and cell death (Chaves et al. 2009; Iseki et al. 2016), pollen sterility and delayed flowering in *Cicer arietinum* (Pushpavalli et al. 2016). Plants have developed a series of salt tolerance mechanisms to avoid these damaging effects. They exclude  $\text{Na}^+$  from roots to reduce uptake and sequester it into vacuoles to protect cytosolic enzymes (Munns and Tester 2008), thus establishing a low cytosolic  $\text{Na}^+ / \text{K}^+$  ratio, with important role for physiological activities and growth under salt stress (Yamaguchi and Blumwald 2005). In our study, 30-51% larger concentrations of  $\text{Na}^+$  in roots and leaves of plants grown under higher soil salinity were accompanied by equally elevated concentrations of  $\text{K}^+$  ions. Consequently, the  $\text{Na}^+ / \text{K}^+$

1 ratio was 43% lower in stems, but showed no difference in roots and leaves (Table 3) of *P. triandra* plants living in higher  
2 soil salinity compared to those from lower soil salinity. This suggests that, in order to maintain the  $\text{Na}^+ / \text{K}^+$  ratio in leaves,  
3 the plants living under higher soil salinity conditions may intensify the  $\text{K}^+$  transport through the stem. The capacity to  
4 reduce  $\text{Na}^+ / \text{K}^+$  ratio in the presence of higher soil salt content, indicates the ability to evolve an efficient salt tolerance  
5 mechanism. In accordance with the present study, Karakas et al. (2017) observed the accumulation of  $\text{Na}^+$  in leaves of *S.*  
6 *soda* and *Portulaca oleracea* under increasing soil salinity content. With respect to other cations, such as  $\text{Mg}^{2+}$  and  $\text{Ca}^{2+}$ ,  
7 in the current study, they accumulated rather in roots than in stem or leaves, which may suggest the presence of an efficient  
8 exclusion mechanism at root level developed to avoid excess accumulation of these ions in the leaves.  
9

10 High EC soil values did not affect significantly the quantum yield ( $F_v'/F_m'$ ) of plants, showing constant values  
11 around 72% in light adapted leaves (fig. 2A). Therefore, oxidative stress induced by salt conditions, did not alter the  
12 function of PSII. Significantly increased accumulation of photosynthetic pigments was observed only for carotenoids (fig.  
13 2C). Carotenoids take part in dissipating excessive excitation energy in PSI and PSII, and in reducing the formation of  
14 harmful singlet oxygen by scavenging it and quenching the excited triplet state of chlorophyll. They also stabilize  
15 chloroplast membranes (Li et al. 2010). Significantly increased concentration of carotenoids in *P. triandra* leaves (by 37%)  
16 in the presence of  $4.45 \text{ dS m}^{-1}$  EC compared to plants living at  $3.14 \text{ dS m}^{-1}$  EC (fig. 2C), corroborates with their antioxidative  
17 role i.e. the protection against photooxidation produced by accumulation of harmful ROS (Das and Roychoudhury 2014).  
18 Furthermore, a series of studies (Rabhi et al. 2012; Zouhaier et al. 2015; Muchate et al. 2016) documented an altering  
19 tendency of chlorophylls and carotenoids content depending on plant species and salt content in the growth media. Fiedor  
20 and Burda (2014) inferred that a high carotenoid content in the pigment complex may play a role in the protection of  
21 chloroplasts from photooxidation and from the deleterious effect of free radicals. Antioxidant role of carotenoids was also  
22 documented by Viljanen et al. (2002) and Li et al. (2010), thus, in our study, greater carotenoids concentrations in leaves  
23 of *P. triandra* growing in higher soil salt suggests that the pigments act as an efficient protective photooxidative  
24 mechanisms.  
25

26 Accumulation of ROS in plants causes a set of harmful effects in the cell. To scavenge the ROS, plants possess  
27 an effective antioxidative system, which involves also several enzymes. Superoxide dismutases are metal containing  
28 enzymes that together with catalases, are extremely important components in catalysing the dismutation of superoxide  
29 radicals into molecular oxygen and water, thus protecting the cell from oxidative damage. In response to salinity several  
30 halophytes accumulate SOD (Parida et al. 2004; Amor et al. 2005; Benzarti et al. 2012; Amjad et al. 2015), but salinity did  
31 not induce SOD accumulation in *Salvadora persica* (Rangani et al. 2016). In the current study, the largest measured  
32 increments of SOD and CAT among ROS enzymes in *P. triandra* under higher salinity ( $4.45 \text{ dS m}^{-1}$ ), suggest that these

two enzymes might play a substantial role in conferring *P. triandra* resistance to superoxide radicals under salt stress. Glutathione transferases may protect plants from oxidative injury by functioning as detoxifying enzymes and also have glutathione peroxidase activity thus being important in the prevention of lipid peroxidation (Roxas et al. 1997; Cummins et al. 1999). The ascorbate peroxidases are components of ascorbate-glutathione cycle, where APX enzymes are key component in catalysing the conversion of hydrogen peroxide into water, using ascorbate as electron donor. Enhanced level of SOD and APX activity in *P. triandra* plants, could be indicators of the elevated ROS levels stimulated by higher salinity. The same tendency was documented by Benzarti et al. (2012) in the halophyte *Atriplex portulacoides* and Parida et al. (2004) in the mangrove *Bruguiera parviflora*. NaCl increased the SOD and GPX activity, but decreased the APX activity in *Salsola crassa* (Yildiztugay et al. 2014) demonstrating that different species choose alternative strategies to adapt to salinity stress. Our results suggest that especially SOD and CAT, but together with APX and GPX play a pivotal protective role against the oxidative stress caused by high salinity, and these enzymes prevent ROS accumulation and thus inhibition or damage of PSII.

Proline accumulation is one of the common physiological responses in higher plants exposed to drought and salinity (Khedr et al. 2003; Székely et al. 2008; Kishor and Sreenivasulu 2014; Per et al. 2017). Proline functions as a possible molecular chaperone in osmotic adjustment and protection of cellular structures, proteins and membranes during osmotic stress in plants (Delauney and Verma 1993; Abid et al. 2018; Zhang and Shi 2018). Proline protects the protein-lipid components of the cell membranes during water stress (Franko and Melo 2000; Szabados and Savoure 2010). It can act as antioxidant, energy metabolism factor and metabolic signal (Anjum et al. 2000; Kartashov 2013). Is able to regulate the metabolite pool and gene expression, and affects plant growth and development (Szabados and Savoure 2010; Eva et al. 2016). Proline is also involved in diminishing photodamage in thylakoidal membranes by scavenging and / or reducing MDA concentration and ROS detoxifying enzymes (Reddy et al. 2004). Proline accumulation in the presence of salinity stress is a well-documented strategy of plants to counteract this adverse environmental condition. Many physiological measurements of different species emphasized an elevated proline level as a response to salt stress (Hong et al. 2000; Székely et al. 2008; Szabados and Savoure 2010). Our study shows that under higher soil salinity *P. triandra* plants displayed a significant increase in the accumulation of free proline compared to lower soil salinity conditions (fig 4A). This result is in accordance with Karakas et al. (2017), who also reported elevation of proline levels in *S. soda* and *P. oleracea* with increasing EC content of soil in greenhouse experiments. The evidence that RWC did not changed significantly in our analysis, shows that accumulation of proline is not a pivotal factor in the control of water status of plants. Moreover, lipid degradation was significantly lower in plants grown under higher than lower soil salinity conditions. This suggests that there are no evident signs of oxidative damage in the cell membrane of *P. triandra* leaves (fig. 4B), and

1 this species possesses an efficient antioxidative defence system in order to scavenge the accumulation of ROS. Same results  
2 were obtained by Karakas et al. (2017) and Rangani et al. (2016) in greenhouse grown halophytes *S. soda* and *S. persica*.  
3  
4 With respect to glycophytes, several authors documented increase in lipid peroxidation as an effect of salinity stress e.g.  
5  
6 *Vigna radiata* (Nazar et al. 2011), *Oryza sativa* (Shobbar et al. 2012), *Solanum melongena* (Shaheen et al. 2013) and *A.*  
7  
8 *thaliana* (Rejeb et al. 2015).  
9

10 Our future studies on the salt adaptation mechanisms of *P. triandra* will focus on the expression pattern of salt  
11 stress regulated genes, which can bring us closer to the salt tolerance strategies of halophytes.  
12  
13

## 14 15 16 **Conclusions**

17  
18 Based on current results, i.e. biomass enhancement under the effect of elevated soil salinity, we suggest that *P. triandra*  
19 not only tolerates, but needs salt for optimal growth and physiological processes in its natural habitat. *P. triandra* acts as a  
20 real halophyte with diverse adaptation strategies to avoid the harmful effect of high soil salinity. Its adaptation mechanisms  
21 include physiological adaptations, maintenance of PSII functional integrity and thus, photosynthetic activity, activation of  
22 efficient antioxidative system, accumulation of osmolyte proline and reduce lipid peroxidation. Understanding the  
23 mechanisms of salt adaptation of *P. triandra*, could be of great importance, possibly leading to the extension of the arable  
24 area of the crop plants by exploiting the biodesalinating capability of this halophyte in Europe and especially in the  
25 Transylvanian Plain.

**Table 1**

Biomass of *Petrosimonia triandra* plants grown under different soil salt concentrations. EC: soil electrical conductivity, FW: fresh weight, DW: dry weight. The values are mean  $\pm$  SD (n = 10), significant values  $p \leq 0.05$ . Significant different means, between the two sampling sites, according to Welch's t test are marked with \* $p = 0.05-0.01$  and \*\* $p = 0.01-0.001$ .

Site no.	EC (dS m <sup>-1</sup> )	Leaf weight (g)		Stem weight (g)		Root weight (g)		Root/shoot ratio	
		FW	DW	FW	DW	FW	DW	FW	DW
1.	3.14	0.67 ( $\pm 0.24$ )	0.23 ( $\pm 0.07$ )	0.62 ( $\pm 0.575$ )	0.25 ( $\pm 0.08$ )	0.43 ( $\pm 0.01$ )	0.12 ( $\pm 0.01$ )	0.34 ( $\pm 0.03$ )	0.26 ( $\pm 0.04$ )
2.	4.45	0.87** ( $\pm 0.44$ )	0.31 ( $\pm 0.31$ )	0.79** ( $\pm 0.08$ )	0.33** ( $\pm 0.08$ )	0.52* ( $\pm 0.02$ )	0.16** ( $\pm 0.02$ )	0.31 ( $\pm 0.04$ )	0.28 ( $\pm 0.05$ )

**Table 2**

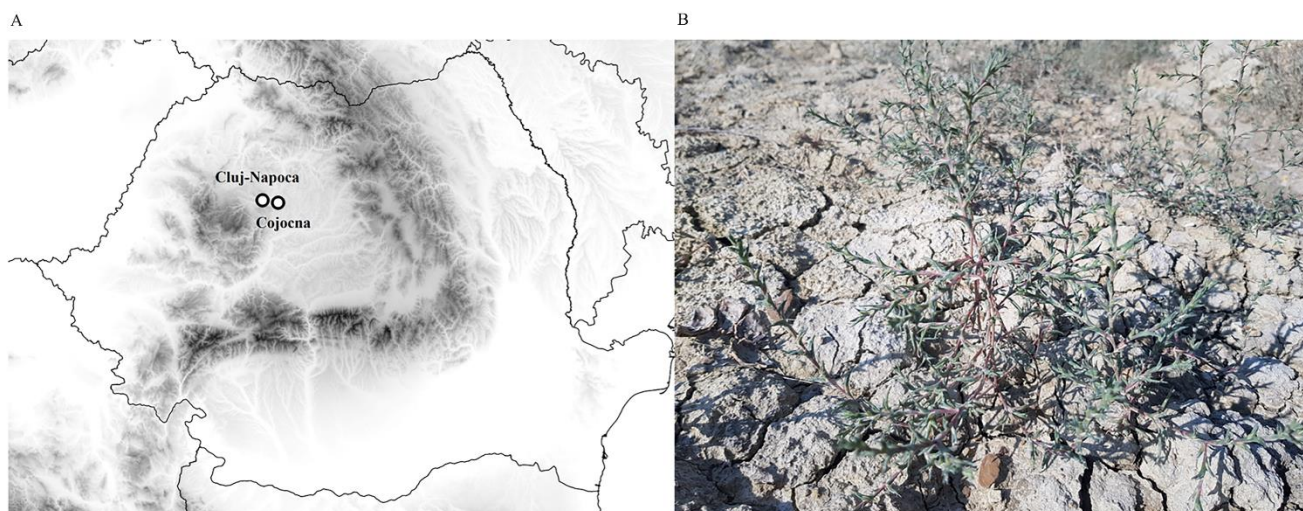

Growth parameters (plant height, leaf area, root length) and relative water content (RWC%) of *Petrosimonia triandra* plants grown in soils with different salinity. EC: soil electrical conductivity. The values are mean  $\pm$  SD (n = 10). Significant different means, between the two sampling sites, according to Welch's t test are marked with \* $p = 0.05-0.01$ .

Site no.	EC (dS m <sup>-1</sup> )	Plant height (cm)	Leaf area (cm <sup>2</sup> )	Root length (cm)	Relative water content (%)
1.	3.14	13.02 ( $\pm 1.3$ )	10.98 ( $\pm 2.64$ )	8.88 ( $\pm 0.96$ )	81.58 ( $\pm 5.43$ )
2.	4.45	16.78* ( $\pm 2.35$ )	18.60* ( $\pm 2.93$ )	11.10 ( $\pm 2.53$ )	69.79 ( $\pm 5.53$ )

**Table 3**

Accumulation of mineral ions in *Petrosimonia triandra* plants grown under different soil salt content. EC: soil electrical conductivity.

Plant tissue	EC (dS m <sup>-1</sup> )	Na <sup>+</sup> (mg kg <sup>-1</sup> DW)	Cl <sup>-</sup> (mg kg <sup>-1</sup> DW)	K <sup>+</sup> (mg kg <sup>-1</sup> DW)	Ca <sup>2+</sup> (mg kg <sup>-1</sup> DW)	Mg <sup>2+</sup> (mg kg <sup>-1</sup> DW)	Na <sup>+</sup> /K <sup>+</sup> ratio

**Fig. 2** PSII efficiency and leaf photosynthetic pigment content of *Petrosimonia triandra* grown in natural habitat, in soils with different salinity. (A) PSII efficiency, (B) chlorophyll *a+b*, (C) carotenoids. Bars represent mean values  $\pm$  SD (n = 10, ns = not significant according to Welch's t test).

**Fig. 3** Specific activity of ROS detoxifying enzymes in *Petrosimonia triandra* plants grown in soils with different salinity. (A) Superoxide dismutase (SOD), (B) Catalase (CAT), (C) Ascorbate peroxidase (APX), (D) Guaiacol peroxidase (GPX) and (E) Glutathione transferase (GST). Bars represent mean values  $\pm$  SD (n = 10). Significant different means according to Welch's t test are marked with \*\*p = 0.01-0.001 and \*\*\*p < 0.001.

**Fig. 4** (A) Proline content and (B) lipid degradation in *Petrosimonia triandra* leaves in the presence of two different saline conditions. Bars represent mean values  $\pm$  SD (n = 10). Significant different means according to Welch's t test are marked with \*\*\*p < 0.001.

## Copyright Transfer Statement

The copyright to this article is transferred to Systems Engineering Society of China and Springer (respective to owner if other than Systems Engineering Society of China and Springer and for U.S. government employees: to the extent transferable) effective if and when the article is accepted for publication. The author warrants that his/her contribution is original and that he/she has full power to make this grant. The author signs for and accepts responsibility for releasing this material on behalf of any and all co-authors. The copyright transfer covers the exclusive right and license to reproduce, publish, distribute and archive the article in all forms and media of expression now known or developed in the future, including reprints, translations, photographic reproductions, microform, electronic form (offline, online) or any other reproductions of similar nature.

An author may self-archive an author-created version of his/her article on his/her own website and or in his/her institutional repository. He/she may also deposit this version on his/her funder's or funder's designated repository at the funder's request or as a result of a legal obligation, provided it is not made publicly available until 12 months after official publication. He/ she may not use the publisher's PDF version, which is posted on [www.springerlink.com](http://www.springerlink.com), for the purpose of self-archiving or deposit. Furthermore, the author may only post his/her version provided acknowledgement is given to the original source of publication and a link is inserted to the published article on Springer's website. The link must be accompanied by the following text: "The final publication is available at [www.springerlink.com](http://www.springerlink.com)".

Prior versions of the article published on non-commercial pre-print servers like arXiv.org can remain on these servers and/or can be updated with the author's accepted version. The final published version (in pdf or html/xml format) cannot be used for this purpose. Acknowledgement needs to be given to the final publication and a link should be inserted to the published article on Springer's website, accompanied by the text "The final publication is available at [springerlink.com](http://springerlink.com)".

The author retains the right to use his/her article for his/her further scientific career by including the final published journal article in other publications such as dissertations and postdoctoral qualifications provided acknowledgement is given to the original source of publication.

The author is requested to use the appropriate DOI for the article. Articles disseminated via [www.springerlink.com](http://www.springerlink.com) are indexed, abstracted and referenced by many abstracting and information services, bibliographic networks, subscription agencies, library networks, and consortia.

After submission of the agreement signed by the corresponding author, changes of authorship or in the order of the authors listed will not be accepted by Systems Engineering Society of China and Springer.

**Table 1**

BIOMASS OF *PETROSIMONIA TRIANDRA* PLANTS GROWN UNDER DIFFERENT SOIL SALT  
CONCENTRATIONS

Site no.	EC (dS m <sup>-1</sup> )	Leaf weight (g)		Stem weight (g)		Root weight (g)		Root/shoot ratio	
		FW	DW	FW	DW	FW	DW	FW	DW
1.	3.14	0.67 (±0.24)	0.23 (±0.07)	0.62 (±0.575)	0.25 (±0.08)	0.43 (±0.01)	0.12 (±0.01)	0.34 (±0.03)	0.26 (±0.04)
2.	4.45	0.87** (±0.44)	0.31 (±0.31)	0.79** (±0.08)	0.33** (±0.08)	0.52* (±0.02)	0.16** (±0.02)	0.31 (±0.04)	0.28 (±0.05)

EC: soil electrical conductivity, FW: fresh weight, DW: dry weight. The values are mean ± SD (n = 10), significant

values  $p \leq 0.05$ . Significant different means, between the two sampling sites, according to Welch's t test are marked with

\* $p = 0.05-0.01$  and \*\* $p = 0.01-0.001$ .

**Table 2**

GROWTH PARAMETERS (PLANT HEIGHT, LEAF AREA, ROOT LENGTH) AND RELATIVE WATER CONTENT (RWC%) OF *PETROSIMONIA TRIANDRA* PLANTS GROWN IN SOILS WITH DIFFERENT SALINITY

Site no.	EC (dS m <sup>-1</sup> )	Plant height (cm)	Leaf area (cm <sup>2</sup> )	Root length (cm)	Relative water content (%)
1.	3.14	13.02 (±1.3)	10.98 (±2.64)	8.88 (±0.96)	81.58 (±5.43)
2.	4.45	16.78* (±2.35)	18.60* (±2.93)	11.10 (±2.53)	69.79 (±5.53)

EC: soil electrical conductivity. The values are mean ± SD (n = 10). Significant different means, between the two sampling sites, according to Welch's t test are marked with \*p = 0.05-0.01.
