Tombácz D, Moldován N, Balázs Z, Gulyás G, Csabai Z, Boldogkői M, Snyder M and Boldogkői Z (2019) Multiple Long-Read Sequencing Survey of Herpes Simplex Virus Dynamic Transcriptome. Front. Genet. 10:834. doi: 10.3389/fgene.2019.00834 Long-read sequencing (LRS) has become increasingly important in RNA research due to its strength in resolving complex transcriptomic architectures. In this regard, currently two LRS platforms have demonstrated adequate performance: the Single Molecule Real-Time Sequencing by Pacific Biosciences (PacBio) and the nanopore sequencing by Oxford Nanopore Technologies (ONT). Even though these techniques produce lower coverage and are more error prone than short-read sequencing, they continue to be more successful in identifying polycistronic RNAs, transcript isoforms including splice and transcript end variants, as well as transcript overlaps. Recent reports have successfully applied LRS for the investigation of the transcriptome of viruses belonging to various families. These studies have substantially increased the number of previously known viral RNA molecules. In this work, we used the Sequel and MinION technique from PacBio and ONT, respectively, to characterize the lytic transcriptome of the herpes simplex virus type 1 (HSV-1). In most samples, we analyzed the poly(A) fraction of the transcriptome, but we also performed random oligonucleotide-based sequencing. Besides cDNA sequencing, we also carried out native RNA sequencing. Our investigations identified more than 2,300 previously undetected transcripts, including coding, and non-coding RNAs, multi-splice transcripts, as well as polycistronic and complex transcripts. Furthermore, we found previously unsubstantiated transcriptional start sites, polyadenylation sites, and splice sites. A large number of novel transcriptional overlaps were also detected. Random-primed sequencing revealed that each convergent gene pair produces non-polyadenylated readthrough RNAs overlapping the partner genes. Furthermore, we identified novel replication-associated transcripts overlapping the HSV-1 replication origins, and novel LAT variants with very long 5' regions, which are co-terminal with the LAT-0.7kb transcript. Overall, our results demonstrated that the HSV-1 transcripts form an extremely complex pattern of overlaps, and that entire viral genome is transcriptionally active. In most viral genes, if not in all, both DNA strands are expressed.

INTRODUCTION

116 Next-generation short-read sequencing (SRS) technology 117 has revolutionized the research fields of genomics and 118 transcriptomics due to its capacity of sequencing a large number 119 of nucleic acid fragments simultaneously at a relatively low cost 120 (Mortazavi et al., 2008; Wang et al., 2009; Djebali et al., 2012). 121 However, SRS technologies have inherent limitations both in 122 genome and transcriptome analyses. This approach does not 123 perform adequately in mapping repetitive elements and GC-rich 124 DNA sequences, or in discriminating paralogous sequences. 125 In transcriptome research, SRS techniques have difficulties in 126 identifying multi-spliced transcripts, overlapping transcripts, 127 transcription start site (TSS), and transcription end site (TES) 128 isoforms, as well as multigenic RNA molecules. 129

Long-read sequencing (LRS) techniques can resolve these 130 obstacles. The LRS technology is able to read full-length RNA 131 molecules, therefore it is ideal for application in the analysis of 132 complex transcriptomic profiles. Currently two techniques are 133 available in the market, the California-based Pacific Biosciences 134 (PacBio) and the British Oxford Nanopore Technologies (ONT) 135 platforms. The PacBio approach is based on single-molecule 136 real-time (SMRT) technology, while the ONT platform utilizes 137 the nanopore sequencing concept. Both techniques have already 138 been applied for the structural and dynamic transcriptomic 139 analysis of various organisms (Byrne et al., 2017; Chen et al., 140 2017; Cheng et al., 2017; Li et al., 2018; Nudelman et al., 2018; 141 Wen et al., 2018; Zhang et al., 2018; Jiang et al., 2019; Zhao 142 et al., 2019), including viruses (Boldogkői et al., 2019b), such 143 as herpesviruses (Tombácz et al., 2015; O'Grady et al., 2016; 144 Tombácz et al., 2016; Balázs et al., 2017a; Balázs et al., 2017b; 145 Moldován et al., 2017b; Tombácz et al., 2017b; Tombácz et al., 146 2017a; Tombácz et al., 2018b; Depledge et al., 2019), poxviruses 147 (Tombácz et al., 2018a), baculoviruses (Moldován et al., 2018b), 148 retroviruses (Moldován et al., 2018a), coronaviruses (Viehweger 149 et al., 2019), and circoviruses (Moldován et al., 2017a). 150 Additionally, the ONT technology is capable of sequencing 151 DNA and RNA in its native form, allowing epigenetic and 152 epitranscriptomic analysis (Wongsurawat et al., 2018; Liu et al., 153 2019; Shah et al., 2019). 154

Herpes simplex virus type 1 (HSV-1) is a human pathogenic 155 virus belonging to the Alphaherpesvirinae subfamily of the 156 Herpesviridae family. Its closest relatives are the HSV-2, 157 the Varicella-zoster virus (VZV), and the animal pathogen 158 pseudorabies virus (PRV). The most common symptom of 159 HSV-1 infection is cold sores, which can recur from latency 160 causing blisters primarily on the lips. HSV-1 may cause acute 161 encephalitis in immunocompromised patients. The ability 162 of herpesviruses to establish lifelong latency within the host 163 organism significantly contributes to their evolutionary success: 164 according to WHO's estimates, more than 3.7 billion people 165 under the age of 50 are infected with HSV-1 worldwide (Looker 166 et al., 2015). 167

HSV-1 has a 152-kbp linear double-stranded DNA genome
 that is composed of unique and repeat regions. Both the long
 (UL) and the short (US) unique regions are flanked by inverted

repeats (IRLs and IRSs, respectively) (Macdonald et al., 2012). 172 The viral genome is transcribed by the host RNA polymerase 173 in a cascade-like manner producing three kinetic classes of 174 transcripts and proteins: immediate-early (IE), early (E), and 175 late (L) (Harkness et al., 2014). IE genes encode transcription 176 factors required for the expression of E and L genes. E genes 177 mainly code for proteins playing a role in DNA synthesis, 178 whereas L genes specify structural elements of the virus. Earlier 179 studies and in silico annotations have revealed 89 mRNAs, 10 180 non-coding (nc)RNAs (Rajčáni et al., 2004; McGeoch et al., 181 2006; Macdonald et al., 2012; Lim, 2013; Hu et al., 2016), and 182 18 microRNAs (Du et al., 2015). Our recent study (Tombácz 183 et al., 2017b) based on PacBio RS II sequencing has identified 184 additional 142 transcripts and transcript isoforms, including 185 ncRNAs. The detection and the kinetic characterization of 186 HSV-1 transcriptome face an important challenge because of 187 the overlapping and polycistronic nature of the viral transcripts. 188 Polycistronic transcription units are different from those of 189 bacterial operons, in that the downstream genes on multigenic 190 transcripts are untranslated because herpesvirus mRNAs use cap-191 dependent translation initiation (Merrick, 2004). The majority of 192 herpesvirus transcripts are organized into tandem gene clusters 193 generating overlapping transcripts with co-terminal TESs. The 194 ul41-44 genomic region of HSV-1 does not follow this rule, 195 since these genes are primarily expressed as monocistronic 196 RNA molecules. Our earlier study has revealed that these genes 197 also produce low-abundance bi- and polycistronic transcripts. 198 Alternatively, many HSV-1 genes, which were believed to be 199 exclusively expressed as parts of multigenic RNAs, have also 200 been shown to specify low-abundance monocistronic transcripts 201 (Tombácz et al., 2017b). 202

SRS technologies have become useful tools for the analysis of 203 transcriptomes. However, conventionally applied SRS platforms 204 cannot reliably distinguish between multi-spliced transcript 205 isoforms, and TSS variants, as well as between embedded 206 transcripts and their host RNAs, etc. Additionally, SRS, even if 207 applied in conjunction with auxiliary techniques such as RACE 208 analysis, has limitations in detecting multigenic transcripts, 209 including polycistronic RNAs and complex transcripts 210 (cxRNAs; containing genes standing in opposite orientations). 211 LRS is able to circumvent these problems. Both PacBio and 212 ONT approaches are capable of reading cDNAs generated 213 from full-length transcripts in a single sequencing run and 214 permit mapping of TSSs and TESs with base-pair precision. 215 The most important disadvantage of LRS compared to SRS 216 techniques is lower coverage. In PacBio sequencing, if any 217 errors occur in raw reads, they are easily corrected thanks to 218 the very high consensus accuracy of this technique (Miyamoto 219 et al., 2014). Thus, it is only a widespread myth that SMRT 220 sequencing is too error prone to be used for precise sequence 221 analysis. The precision of basecalling is substantially lower for 222 ONT platform than that of PacBio, but the former technique 223 is far more cost-effective, and yields both higher throughput 224 and longer reads. The high error rate of the ONT technique 225 can be circumvented by obtaining high sequence coverage. 226 Nonetheless, this latter problem is not critical in transcriptome 227

²²⁸

229 research if the genome sequence of the examined organism has already been annotated. 230

A diverse collection of methods and approaches have 231 already been employed for the investigation of herpesvirus 232 transcriptomes, including in silico detection of open reading 233 frames (ORFs) and cis-regulatory motifs, Northern-blot 234 analysis (Costa et al., 1984; Sedlackova et al., 2008), S1 235 nuclease mapping (McKnight, 1980; Rixon and Clements, 236 1982), primer extension (Perng et al., 2002; Naito et al., 2005), 237 real-time reverse transcription-PCR (RT²-PCR) analysis 238 (Tombácz et al., 2009), microarrays (Stingley et al., 2000), 239 Illumina sequencing (Harkness et al., 2014; Oláh et al., 2015), 240 PacBio RS II (O'Grady et al., 2016; Tombácz et al., 2017b), and 241 Sequel sequencing, as well as ONT MinION cDNA and direct 242 243 RNA sequencing (Boldogkői et al., 2018; Prazsák et al., 2018; Depledge et al., 2019). 244

In this study, we report the application of PacBio Sequel 245 and ONT MinION long-read sequencing technologies for the 246 characterization of the HSV-1 lytic transcriptome. We used an 247 amplified isoform sequencing (Iso-Seq) protocol of PacBio that 248 was based on PCR amplification of cDNAs prior to sequencing. 249 We used both cDNA and direct (d)RNA sequencing on the 250 ONT platform. Additionally, we applied Cap-selection for 251 ONT sequencing. In order to identify non-polyadenylated 252 transcripts, we also applied random oligonucleotide primer-253 based RT in addition to the oligo(dT)-priming. Furthermore, 254 the latter technique is more efficient for the mapping of the 255 TSSs, and it is useful for the validation of novel RNA molecules. 256 Our intentions of using novel LRS techniques were to analyze 257 the dynamic viral transcriptome, to generate a higher number 258 of sequencing reads, and to identify novel transcripts that had 2.59 been undetected in our earlier PacBio RS II-based approach. 260 Furthermore, in this report, we also reanalyzed our earlier 261 results that were obtained using a single-platform method 262 (Tombácz et al., 2017b). 263

MATERIALS AND METHODS

Cells and Viral Infection

264

265

266

267

273

274

The strain KOS of HSV-1 was propagated on an immortalized 269 kidney epithelial cell line (Vero) isolated from the African 270 green monkey (Chlorocebus sabaeus). Vero cells were cultivated 271 in Dulbecco's modified Eagle medium supplemented with 272

10% fetal bovine serum (Gibco Invitrogen) and 100 µl 286 penicillin-streptomycin 10K/10K mixture (Lonza)/ml and 287 5% CO₂ at 37°C. The viral stocks were prepared by infecting 288 rapidly-growing semi-confluent Vero cells at a multiplicity of 289 infection (MOI) of 1 plaque-forming unit (pfu)/cell, followed 290 by incubation until a complete cytopathic effect was observed. 291 The infected cells were then frozen and thawed three times. 292 The cells were then centrifuged at 10,000 ×g for 15 min 293 using low-speed centrifugation. For the sequencing studies, 294 cells were infected with MOI = 1, incubated for 1 h. This 295 was followed by removal of the virus suspension and a PBS 296 washing step. Next, the cells were supplied with a fresh culture 297 medium and were then incubated for 1, 2, 4, 6, 8, 10, 12, or 24 h. 298

RNA Isolation

The total RNA samples were purified from cells using the NucleoSpin[®] RNA kit (Table 1) according to the kit's manual and our previously described methods (Boldogkői et al., 2018). The RNA samples were quantified using the Qubit® 2.0 Fluorometer and were stored at -80°C until use. The samples taken from each experiment were then mixed for sequencing. Samples were subjected to ribodepletion for the random primed sequencing, while selection of the poly(A)⁺ RNA fraction was being carried out for polyA-sequencing. All experiments were performed in accordance with the relevant guidelines and regulations.

Pacific Biosciences RS II and Sequel Platforms—Sequencing of the Polyadenylated RNA Fraction or the Total Transcriptome

The Clontech SMARTer PCR cDNA Synthesis Kit was used 318 for cDNA preparation according to the PacBio Isoform 319 Sequencing (Iso-Seq) protocol. For the analysis of relatively 320 short viral RNAs, the 'No-size selection' method was used 321 and samples were run on the RSII and Sequel platforms, both. 322 The SageELF™ and BluePippin™ Size-Selection Systems 323 (Sage Science) were also used to carry out size-selection for capturing the potential long, rare transcripts. The reverse 325 transcription (RT) reactions were primed by using the oligo(dT) from the SMARTer Kit. However, we also used 327 random primers for a non-size selected sample to detect 328 non-polyadenylated RNAs. The cDNAs were amplified by 329

343 the KAPA HiFi Enzyme from KAPA Biosystems, according to PacBio's recommendations (Balázs et al., 2017b; Tombácz 344 et al., 2018b). The SMRTbell libraries were generated 345 346 using PacBio Template Prep Kit 1.0. For binding the DNA polymerase and annealing the sequencing primers, the DNA/ 347 Polymerase Binding Kit P6-C4 and v2 primers, as well as the 348 Sequel Sequencing Kit and v3 primers were used for the RSII 349 and Sequel sequencing, respectively. The DNA/Polymerase 350 Binding Kit P6-C4 and v2 primers were used for binding DNA 351 polymerase and for annealing sequencing primers. Whereas, 352 the Sequel Sequencing kit and v3 primers were used for RSII 353 and Sequel sequencing. 354

The polymerase-template complexes were bound to MagBeads with the PacBio MagBead Binding Kit. Samples were loaded onto the RSII SMRT Cell 8Pac v3 or Sequel SMRT Cell 1M. The movie time was 240 or 360 min *per* SMRT Cell for the RSII, while 600-min movie time was set to the Sequel run.

³⁶² Oxford Nanopore Minion Platform—cDNA ³⁶³ Sequencing Using Oligo(dT) ³⁶⁴ or Random Primers

Regular (No Cap Selection) Protocol

The 1D Strand switching cDNA by ligation protocol (Version: 367 SSE_9011_v108_revS_18Oct2016) from the ONT was used for 368 sequencing HSV-1 cDNAs on the MinION platform. The ONT 369 Ligation Sequencing Kit 1D (SQK-LSK108) was applied for 370 the library preparation using the recommended oligo(dT) 371 primers, or custom-made random oligonucleotides, as well as 372 the SuperScipt IV enzyme for the RTs. The cDNA samples were 373 subjected to PCR reactions with KAPA HiFi DNA Polymerase 374 (Kapa Biosystems) and Ligation Sequencing Kit Primer Mix 375 (part of the 1D Kit). The NEBNext End repair/dA-tailing 376 Module (New England Biolabs) was used for the end repair, 377 whereas the NEB Blunt/TA Ligase Master Mix (New England 378 Biolabs) was utilized for the adapter ligation. The enzymatic 379 steps (e.g.: RT, PCR, and ligation) were carried out in a 380 Veriti Cycler (Applied Biosystems) according to the 1D 381 protocol (Moldován et al., 2018b; Tombácz et al., 2018b). The 382 Agencourt AMPureXP system (Beckman Coulter) was used 383 for the purification of samples after each enzymatic reaction. 384 The quantity of the libraries was checked using the Qubit 385 Fluorometer 2.0 and the Qubit (ds)DNAHS Assay Kit (Life 386 Technologies). The samples were run on R9.4 SpotON Flow 387 Cells from ONT. 388

390 Cap Selection Protocol

The TeloPrime Full-Length cDNA Amplification Kit (Lexogen) 391 was used for generating cDNAs from 5' capped polyA⁽⁺⁾ 392 RNAs. RT reactions were carried out with oligo(dT) primers 393 (from the kit) or random hexamers (custom made) using the 394 enzyme from the kit. A specific adapter (capturing the 5' cap 395 structure) was ligated to cDNAs (25°C, overnight), then the 396 samples were amplified by PCR using the Enzyme Mix and the 397 Second-Strand Mix from the TeloPrime Kit. The reactions were 398 399

performed in a Veriti Cycler and the samples were purified on 400 silica membranes (TeloPrime Kit) after the enzymatic reactions. 401 The Qubit 2.0 and the Qubit dsDNA HS quantitation assays 402 (Life Technologies) were used for measuring the concentration 403 of the samples. A quantitative PCR reaction was carried out for 404 checking the specificity of the samples using the Rotor-Gene Q 405 cycler (Qiagen) and the ABsolute qPCR SYBR Green Mix from 406 Thermo Fisher Scientific. A gene-specific primer pair (HSV-1 407 us9 gene, custom made) was used for the test amplification. 408 The PCR products were used for ONT library preparation and 409 sequencing. The end-repair and adapter ligation steps were 410 carried out as was described in the 'Regular' protocol, and in 411 our earlier publication (Boldogkői et al., 2018). The ONT R9.4 412 SpotONFlow Cells were used for sequencing. 413

Application of Terminator Exonuclease

Some of the non-Cap-selected samples were treated by 4 Terminator exonuclease (Epicentre/Lucigen) in order to reduce 4 the proportion of sequencing reads with incomplete 5'-UTR 4 regions. The protocol has been carried out as recommended by 4 the manufacturer. Briefly, 2 μ l of buffer A, 1 μ g of total RNA, 0.5 μ l 4 of RNaseOUT (Invitrogen), and 1 U of Terminator exonuclease were mixed and incubated at 30°C for 60 min. The same reaction 4 was carried out using buffer B instead of buffer A, after which the two mixtures were pooled. 4

Oxford Nanopore Minion Platform – Direct RNA Sequencing

The ONT's Direct RNA sequencing (DRS) protocol (version: DRS_9026_v1_revM_15Dec2016) and the ONT Direct RNA Sequencing Kit (SQK-RNA001) were used to examine the transcript isoforms without enzymatic reactions—to avoid the potential biases—as well as to identify possible base modifications alongside the nucleotide sequences. Polyadenylated RNA was extracted from the total RNA samples and it was subjected to DRS library preparation according to the ONT's protocol (Boldogkői et al., 2018). The quantity of the sample was measured by Qubit 2.0 Fluorometer using the Qubit dsDNA HS Assay Kit (both from Life Technologies). The library was run on an ONT R9.4 SpotON Flow Cell. Basecalling was carried out using Albacore (v 2.3.1).

Mapping and Data Analysis

The minimap2 aligner (Li, 2018) was used with options -ax splice -Y -C5 –cs for mapping the raw reads to the reference genome (X14112.1), followed by the application of the LoRTIA toolkit (https://github.com/zsolt-balazs/LoRTIA) for the determination of introns, the 5' and 3' ends of transcripts, as well as for detecting the full-length reads. Putative introns were defined 449 as deletions with the consensus flanking sequences (GT/AG, 450 GC/AG, AT/AC). The complete intron lists are available as 451 additional material. We used even stricter criteria: only those 452 splice sites were accepted, which were validated by dRNA-Seq 453 [used in our present work and in Depledge and coworkers' 454 study (Depledge et al., 2019)]. These transcripts all have the 455

562

563

564

canonical splice site: GT/AG and they are abundant (> 100 read 457 in Sequel data). 458

The 5' adapter and the poly(A) tail sequences were 459 460 identified at the ends of reads by the LoRTIA toolkit based on Smith-Waterman alignment scores (Table 2). If the adapter 461 or poly(A) sequence ended at least three nucleotides (nts) 462 downstream from the start of the alignment, the adapter was 463 discarded, as it could have been placed there by template-464 switching. Transcript features such as introns, transcriptional 465 start sites (TSS) and transcriptional end sites (TES) were 466 annotated if they were detected in at least two reads and in 467 0.1% of the local coverage. In order to reduce the effects of 468 RNA degradation, only those TSSs were annotated, which 469 were significant peaks compared to their ±50-nt-long 470 windows according to Poisson distribution. Reads being 471 connected a unique set of transcript features were annotated 472 as transcript isoforms. Low-abundance reads detected in a 473 single experiment were accepted as transcripts if the same 474 TSS and TES were also used by other transcripts. In most 475 cases, those reads were accepted as isoforms, which were 476 detected in at least two independent experiments. The 5'-ends 477 of the long low-abundance reads were checked individually 478 using the Integrative Genome Viewer (IGV; https://software. 479 broadinstitute.org/software/igv/download). The workflow of 480 the data analysis can be found in **Supplementary Figure 1**. 481

Analysis of the HSV-1 Transcriptome With Full-Length Sequencing

In this work, we report the application of two distinct LRS techniques (the PacBio Sequel and the ONT MinION platforms), and multiple library approaches for the investigation of the HSV-1 lytic transcriptome. We also reutilized our previous PacBio RS II data for the validation of novel transcripts. The PacBio sequencing is based on an amplified Iso-Seq template preparation protocol that utilizes a switching mechanism at the 5' end of the RNA template, and is thereby able to produce complete full-length cDNAs (Zhu et al., 2001). We applied both cDNA and dRNA sequencing for the ONT technique. Additionally, we used Cap-selection for a fraction of samples. A single sample was treated by Terminator exonuclease, which selectively degrades uncapped and non-polyadenylated transcripts. ONT sequencing was also used for the kinetic analysis of HSV-1 gene expressions. Sequencing reads were mapped to the HSV-1

(X14112) genome using the Minimap2 alignment tool (Li, 2018) 514 with default parameters. 515

Altogether, we obtained 80,061 full-length ROIs mapping to 516 the HSV-1 genome using Sequel sequencing, whereas PacBio 517 RSII platform generated 38,972 ROIs (Supplementary Table 1). 518 ONT sequencing produced altogether 1,505,848 sequencing 519 reads mapping to the viral genome. The reason behind the 520 relatively low proportion of the full-length read count within the 521 MinION samples is that this method-compared to PacBio-522 generates a higher number of 5' truncated reads. We and 523 others have reported in previous publications that the dRNA-524 Seq method is not optimal for capturing entire transcripts 525 (Moldován et al., 2017b; Moldován et al., 2018b; Workman 526 et al., 2018): we found that short 5' sequences of transcripts 527 and in many cases the polyA-tails were missing from most of 528 the reads. However, a recently published technique utilizing 529 adapter ligation to the 5' end of full-length mRNAs is able to 530 solve this problem (Jiang et al., 2019). Another drawback of 531 native RNA sequencing is its low throughput compared to 532 cDNA sequencing. The advantage of dRNA-Seq is that it is free 533 of false products which are typically produced by RT, PCR, and 534 cDNA sequencing. 535

Table 3 shows the average read lengths of mapped full-length ROIs and MinION reads in the different samples. A detailed description of reads obtained from all libraries is found in Supplementary Table 1.

TABLE 3 | Average mapped read-lengths and transcript lengths.

Technique	Average length of the reads (bp)	Average length of the abundant full-length transcripts (bp)

644

645

571 Cap-selection performed suboptimally in our experiment, because it produced relatively short average sequencing reads. 572 Random RT-priming allowed the analysis of non-polyadenylated 573 574 transcripts and helped the validation of TSSs and splice sites. Additionally, this technique proved to be superior for identifying 575 the 5'-ends of very long transcripts, including polycistronic and 576 complex RNA molecules. Terminator exonuclease was used for 577 the enrichment of intact TSSs of the transcripts. 578

The following technical artifacts can be generated by RT and 579 PCR: template switching, and nonspecific binding of oligod(T) 580 or PCR primers. In addition to poly(A) tails, oligo(dT) primers 581 occasionally hybridize to A-rich regions of transcripts and 582 thereby produce false reads. These products were discarded 583 from further analysis, albeit in some cases we were unsure 584 about the non-specificity of the removed reads. We ran 585 altogether 11 parallel sequencing reactions using 8 different 586 techniques for providing independent reads. Additionally, in 587 some cases, the same TSS, TES or splice junctions were found 588 in other transcripts detected within the same sequencing 589 reaction which further enhanced the number of independent 590 sequencing reads. In our earlier publication (Tombácz et al., 591 2017b), we could not detect all spurious products, therefore, 592 in the present work, we have made a minor correction to our 593 formerly published results. 594

We used a novel bioinformatics tool (LoRTIA) 595 developed in our laboratory - for the identification of TSS 596 and TES positions, as well as splice donor and acceptor sites 597 (Supplementary Figure 1). This software suite detected a total of 598 1,677 putative TSSs 162 putative TESs and 379 putative introns 599 (Supplementary Table 2). A putative TSS or TES was accepted 600 as real if LoRTIA detected it in at least three independent 601 samples in the case of longer isoforms, and five independent 602 samples in the shorter variants, including 5'-truncated ORF-603 containing RNAs. The reason for a more stringent selection 604 criterion for the short isoforms is that these can be the result 605 of fragmentation, which is not the case for longer isoforms. 606 These analyses yielded altogether 537 TSSs and 77 TESs. Only 607 those sequencing reads were accepted as transcripts, which 608 contained a TSS and a TES annotated in the above way. This 609 method yielded 667 transcripts (Supplementary Table 3). 610 For very long transcripts (\geq 3,000 bp), we applied a different 611 rule: a read was accepted as a transcript if it was longer than 612 all annotated overlapping transcripts even if it was represented 613 in a few copies and had no annotated TSS. A large number 614 of very long transcripts were identified this way in most cases 615 in the Sequel dataset. Thus, altogether 2,250 transcripts were 616 identified in this study (Supplementary Table 3). We assume 617 that much more low-abundance and very long transcripts 618 are expressed by the HSV-1 genome than we detected with 619 our very strict criteria. Our dataset is available for further 620 621 investigations, which can confirm or reject these latter categories of putative transcripts. 622

For intron identification, we used the following criteria: the candidate intron had to carry one of the canonical splice junction sequences: GT/AG, GC/AG, AT/AC; and it had to be detected by dRNA-Seq and both cDNA-Seqs (PacBio and CARC) ONT platforms). Besides introns based on hard evidence, we 628 enlist additional putative introns of which the criterion was 629 their detection by both dRNA-Seq and at least one of the cDNA 630 (PacBio or ONT) sequencings. The third category of introns 631 includes very abundant splice variants and introns on very 632 long transcripts that were exclusively identified using Sequel 633 sequencing in most cases. This study identified a large number 634 of rare variants with deletions, which represented less than 635 5% of the total isoforms of a certain transcript. These putative 636 splice variants were not accepted as transcripts. Altogether, 182 637 introns were identified in terms of the above criteria, among 638 which 155 carry canonical GT/AG, 22 GC/AG, and 2 AT/ 639 AC splice junction sequences (Supplementary Table 2). Our 640 analysis detected 80 transcripts containing one or more of these 641 introns (Supplementary Table 3). 642

In Silico Analysis of Promoters and Poly(A) Signals

In order to detect promoter sequences, we analyzed the 646 -150 to +1 upstream region of the TSSs in silico (Figure 1). 647 We found that 45% (371) of the TSSs are preceded by a 648 canonical GC box sequence at a mean distance of 66.301nt 649 (σ = 31.205), 4% (35) by a CAAT box at a mean distance of 650 113.428nt (σ = 15.471), and 11% (91) by a TATA box at a 651 mean distance of 30.373nt (σ = 2.058) (Mackem and Roizman, 652 1982; Guzowski and Wagner, 1993). Some of the GC boxes 653 may be nonfunctional, since they may be the result of the 654 high GC-content of the viral genome. Earlier studies found 655 a canonical initiator region (INR) ± 5 nt around the TSS 656 of eukaryotic organisms (Lim et al., 2004; Xi et al., 2007). 657 These have been shown to be used during the early viral 658 gene expression, whereas late transcription is initiated from a 659 G-rich sequence (Huang et al., 1996; Lieu and Wagner, 2000). 660 We detected 16 TSSs containing a CAG INR (TSS position 661 underlined) and 89 TSSs having YANW (Y: cytosine/thymine, 662 N: adenine/cytosine/thymine/guanine, W: thymine/adenine, 663 TSS position underlined). 664

We found that TSSs expressed in every time point are 665 abundant and their INRs exhibit high similarity to canonical 666 eukaryotic INRs, whereas TSSs from late samples are similar to 667 the VP5 promoter (Figure 1A). Furthermore, these late TSSs 668 are expressed in low abundance (2.8% of all reads starting in 669 these positions) but their ratio is seven-fold higher than those 670 of early TSSs (Figure 1B). We carried out in silico analysis of 671 the -50nt region located upstream the TESs and detected 59 672 possible polyadenylation signals (PASs) at a mean distance 673 of 21.779nt (σ = 5.558). The number of TESs expressed in 674 both early and late phases is slightly higher than the number 675 of TESs expressed only in the late phase of the viral life cycle 676 (Figure 1C). TESs expressed throughout the entire viral 677 replication are characterized by canonical PASs, cleavage signals 678 and GU-rich regions. This is in contrast with TESs expressed 679 only in the late phase, which tend to have no canonical signals 680 for polyadenylation and cleavage (Figure 1D). Additionally, 681 these late TESs are low abundance, representing only 0.1% of 682 the reads' 3' ends. 683

Frontiers in Genetics | www.frontiersin.org

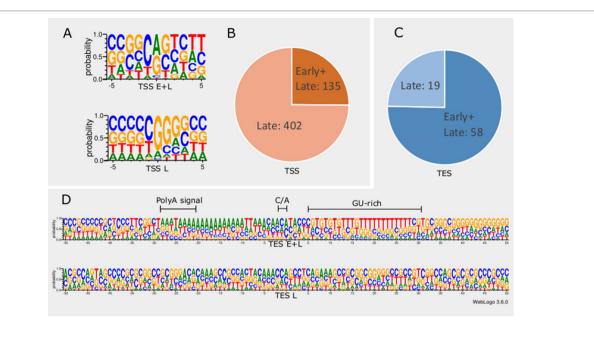

FIGURE 1 | In silico analysis of INR and PAS sequences. (A) The initiator region (INR) of early samples is similar to the canonical eukaryotic INR sequence, while late INRs show homology with the VP5 promoter. (B) The proportion of TSSs present in both early and late or exclusively late time points of infection. (C) The proportion of TESs present in both early and late or exclusively late time points of infection. (D) The probability of expression of nucleotides in the ±50nt region of TESs throughout the entire infection period compared to those nucleotides that expressed only in late time points. TESs expressed during the entire period of infection (E+L) contain a canonical poly(A) signal, the C/A cleavage site and GU-rich downstream region. Late TESs lack a PAS and the canonical downstream elements, but they contain a GC-rich sequences 15-20nt downstream of the cleavage site.

Novel Putative mRNAs

5'-Truncated transcriptional reads were accepted as transcripts if they were present in at least five independent samples. The first base had to be located within a ±5 window range. Additionally, reads having less than a 5% proportion at the overlapping region were discarded. Present investigations revealed 182 novel 5'-truncated mRNAs (tmRNAs) of HSV-1 (Supplementary Table 4), which were all produced from genes embedded in larger host genes of the virus. These 5'-truncated mRNAs are assumed to be generated by alternative transcription initiation from promoters located within larger genes. We could identify promoter modules for only 39 transcripts (we could not identify promoter consensus sequences for several canonical ORFs, too). These transcripts all contain in-frame ORFs. The first in-frame AUG triplet is assumed to encode the translation start codon. Further analyses have to be carried out to verify the coding potential of the ORF-containing tmRNAs. We detected a transcript - termed 'RL-intron' (RL2I) - with a TSS identical to that of the TSS of *rl2* gene but with a TES located within the intronic region of this gene. Our BLAST searches resulted in hypothetical proteins predicted to this ORF, but according to our knowledge, no such transcript has been detected until now.

Novel Putative Non-Coding (or Coding) Transcripts

In this part of our study, we detected 18 putative non-coding RNAs, including antisense RNAs (asRNAs, termed as ASTs)

and other putative long non-coding RNAs (lncRNAs) (Table 4). Furthermore, we validated and determined the base pairprecision termini of the transcripts published earlier by us and

by others. **Supplementary Table 5** shows the potential peptides encoded by the ORFs on these transcripts. Further studies have to confirm whether these ORFs are translated. If so, they are novel protein-coding genes.

(1) Antisense RNAs These transcripts can be controlled 803 by their own promoters or by the promoter of another 804 (mRNA) gene. It has earlier been reported that the 0.7-kb LAT 805 transcript is not expressed in strain KOS of HSV-1 (Zhu et al., 806 1999). Here we demonstrate that this is not the case, since we 807 were able to detect this transcript. The existence of the shorter 808 LAT-0.7kb-S (Tombácz et al., 2017b) was also confirmed. 809 Additionally, we detected asRNAs being co-terminal with 810 the LAT-0.7 transcripts, but having much longer TSSs. The 811 LAT region and its surrounding genomic sequences are 812 illustrated in Figure 2A. Using random oligonucleotide-based 813 LRS techniques, we obtained a large number of antisense-814 oriented reads, most of them without identified 5'-ends. We 815 also detected antisense transcripts without defined TSSs 816 and TESs within 27 HSV-1 genes (rl1, rl2, ul1, ul2, ul4, ul5, 817 ul10, ul14, ul15, ul19, ul23, ul29, ul31, ul32, ul36, ul37, ul39, 818 ul42, ul43, ul44, ul49, ul50, ul53, ul54, us4, us5, us8). The 819 expression level of these asRNAs is low, in most cases only 820 a few reads were detected per gene locus. However, a high 821 level of antisense RNA expression was identified within the 822 locus of *ul10* gene. A special class of asRNAs is produced by 823 divergent genes, and read-through RNAs (rtRNAs) generated 824 by transcriptional read-through between convergent gene 825 pairs. These transcripts are mRNAs with long stretches of 826 antisense segments. For example, we detected an antisense 827 transcript originated within the 3' region of ul4 gene and 828 co-terminated with UL6-7 bicistronic transcript. This RNA 829 molecule contains three splice sites, and can be considered as 830 a very long TSS isoform of the UL6-7 transcript. 831

(2) Intergenic ncRNAs A ncRNA (termed "intergenic 832 ncRNA"; IGEN-1) located between the ul26 and ul27 genes was 833 also identified. This transcript is co-terminal with the UL27-AT 834 RNA, which is a longer TES isoform of UL27 transcript 835 (Figure 2B). Another non-coding transcript (IGEN-2) with 836 unidentified transcript ends was detected to be expressed in the 837 outer termini of the HSV-1 unique long region. The potential 838 function of IGEN transcripts remains unclear. A bidirectional, 839 low-level expression from the intergenic region between the *rl2* 840 (icp0) and LAT genes was also observed. These RNA molecules 841 are co-terminal with the LAT-0.7kb transcript and may be parts 842 of the potential RL2-LAT-UL1-2-3 transcript (Tombácz et al., 843 2017b). Additionally, we detected RNA expression in practically 844 every intergenic region. 845

(3) Intra-intronic ncRNAs A ncRNA was identified within
the intron of the *rl2* gene, which was designated as NCIRL2. This
transcript is expressed in a low abundance.

850 Replication-Associated Transcripts

We identified five replication-associated RNAs (raRNAs) designated OriL-RNA1-2, and OriS-RNA1-3, which overlap the replications origins OriL and OriS, respectively. OriL-RNA1 is a long TSS isoform produced from the *ul30* gene, whereas OriS-RNA2 is a TSS variant of rs1 (icp4) (Figure 3). OriL-RNA2 856 is a transcript without an annotated TES. We suppose that this 857 transcript is the long TSS variant of the *ul29* gene. We were only 858 able to detect certain segments but not the entire OriS-RNA1 859 described by Voss and Roizman (1988). We also detected a longer 860 TSS isoform of the us1 gene (US1-L2 = OriS-RNA3) which 861 overlaps the OriS located within the terminal repeat of US region 862 (TRS) (Figure 3). Additionally, OriS is also overlapped by a longer 863 5' variant of the us12 gene (US12-11-10-L2 = OriS-RNA-4). 864

TSS and TES Isoforms

The multiplatform system allowed the discovery of novel 867 RNA isoforms and reannotation of the transcript termini 868 published earlier by others and us (Tombácz et al., 2017b; 869 Depledge et al., 2019). The LoRTIA software suit - used for 870 the detection of TSS and TES positions - identified 218 TSS 871 and 56 TES positions (Supplementary Table 2). Altogether 872 53 genes produce at least one TSS isoform, besides the most 873 frequent variants (Supplementary Table 3). Fifteen genes 874 were found to produce three different transcript length 875 isoforms (including the most frequent versions). The recent 876 LRS analysis discovered 51 protein-coding and 2 (0.7 kb 877 LAT, and RS1) non-coding transcripts with alternative TSSs. 878 However, a few transcripts with unannotated 5'-ends were also 879 detected (Supplementary Table 3). The alternative TSSs may 880 lead to transcriptional overlap or they may enlarge the extent 881 of existing overlaps especially between divergently transcribed 882 genes. Some transcripts (e.g. UL19 and UL10) exhibit an 883 especially high complexity of TSS isoforms (Figure 4A). 884 The ul21 gene produces nine different 5' length variants, 885 the longer ones overlap the divergently oriented *ul22* gene) 886 (Figure 4B). Additionally, long TSS isoforms are responsible 887 for the overlaps of each replication origin of HSV-1, which is 888 not the case in PRV, its close relative (Tombácz et al., 2015; 889 Boldogkői et al., 2019a). Many of the longer TSS variants 890 contain upstream ORFs (uORFs), which may carry distinct 891 coding potentials as described by Balázs and colleagues in 892 the human cytomegalovirus (Balázs et al., 2017a). Two novel 893 3'-UTR variants were also identified in this study. 894

Novel Splice Sites and Splice Isoforms

In this study, we also used dRNA sequencing, which provides 897 a fundamentally different method from cDNA sequencing 898 and hence can be utilized to filter out spurious splice sites. 899 The splice donor and acceptor sites were also detected by 900 using the LoRTIA tool. Altogether, using different sequencing 901 techniques and bioinformatics analyses, we were able to verify 902 the existence of 5 previously described and 30 novel splice 903 sites. Table 5 contains the list of introns, which were confirmed 904 by dRNA-Seq (Figure 5). By far the most complex splicing 905 pattern was detected in RNAs produced from the ul41-45 906 genomic region. 907

Novel Multigenic Transcripts

Our earlier survey has revealed several novel multigenic RNAs, ₉₁₀ including polycistronic and complex transcripts (Tombácz ₉₁₁

908

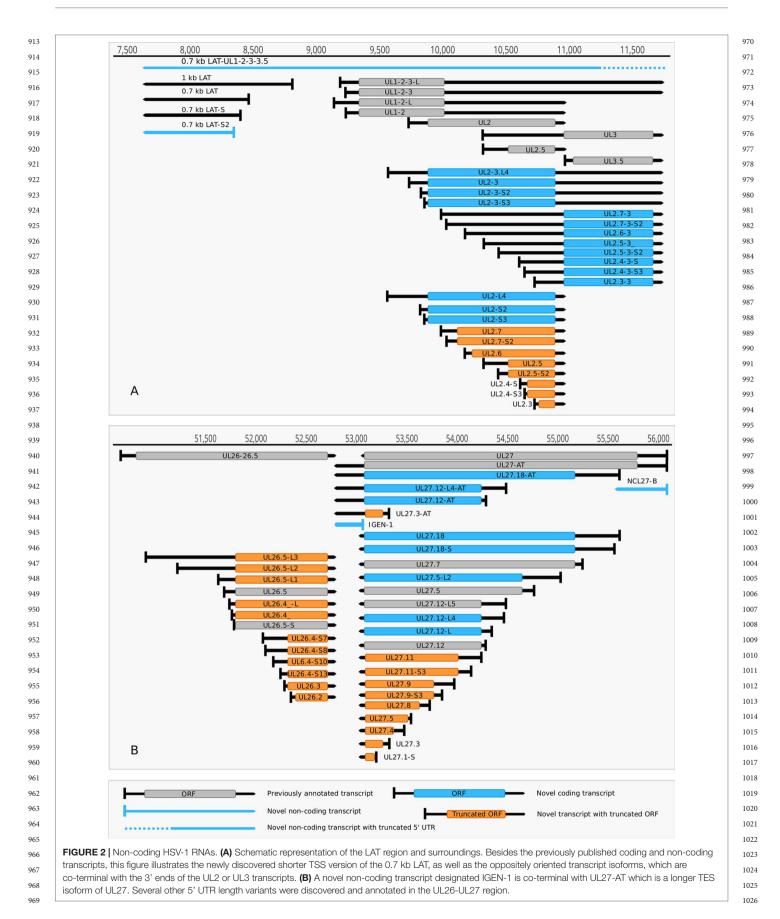

909

895

896

865

866

Frontiers in Genetics | www.frontiersin.org

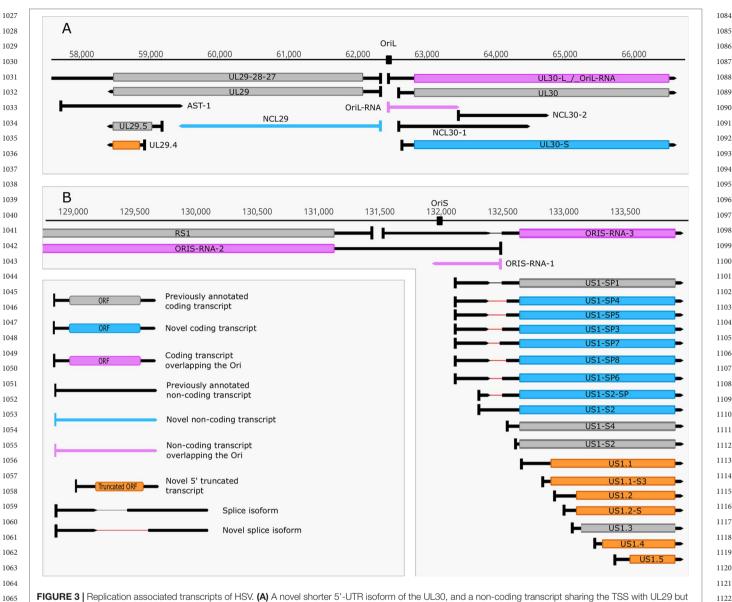

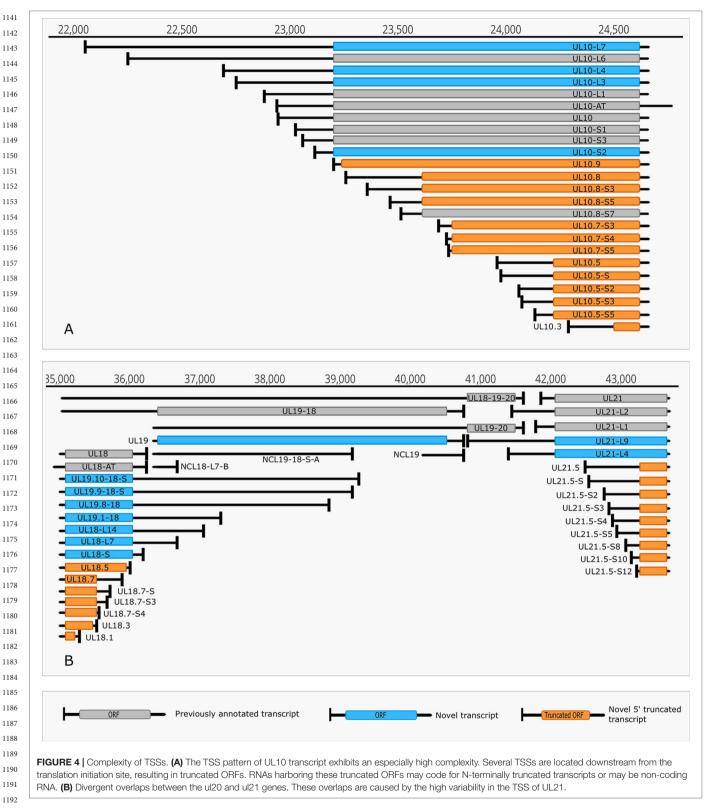

FIGURE 3 | Replication associated transcripts of HSV. (A) A novel shorter 5'-UTR isoform of the UL30, and a non-coding transcript sharing the TSS with UL29 but terminating within its ORF was discovered in the vicinity of Ori-L. (B) Two isoforms with shorter 5'-UTRs, seven splice isoforms and six novel putative protein-coding transcripts were annotated downstream of Ori-S

et al., 2017b). In this work, we identified 201 multigenic transcripts containing two or more genes (Supplementary Table 3). The cxRNAs are long RNA molecules with at least 2 genes standing in opposite orientation relative to one another. Our intriguing findings are the RL1-RL2 (ICP34,5-ICP0) bicistronic transcript, as well as the 0.7. kb LAT-UL1-2-3-3.5 cxRNA (Figures 2A, B). Most of the novel multigenic transcripts are expressed at low levels, which can explain why they had previously gone undetected. In this work, we also identified four novel complex transcripts (0.7 kb LAT-UL1-2-c, UL18-15.5-c, UL20-21-c, US4-3-2-c) with unannotated TSSs (Figure 2A). We were able to detect these transcripts by cDNA sequencing and by the reanalysis of a MinION dRNA sequencing dataset (Depledge et al., 2019). Our novel

experiments validated previously published cxRNAs. This study demonstrates that full-length overlaps between two divergently-oriented HSV-1 genes are an important source for the cxRNA molecules. The likely reason for the lack of cxRNA TSSs in many cases is that they are very long and low-abundance transcripts. It cannot be excluded with absolute certainty that some of the low-abundance multigenic transcripts are artefacts produced by the template-switch mechanism; other approaches are needed for the validation of their existence one-by-one.

Novel Transcriptional Overlaps

This study revealed an immense complexity of transcriptional overlaps (Figure 6 and Table 6). These overlaps are produced by

either transcriptional read-through events between transcripts oriented in parallel [as described in Kara et al. (2019)], or in a convergent manner (thereby generating rtRNAs), or through the use of long TSS isoforms pertaining to one or of both partners

of divergently-oriented genes. Transcriptional overlaps can also be produced by antisense transcripts controlled by their own promoters, as seen in LAT transcripts. Besides the 'soft' (alternative) overlaps, adjacent genes can also produce 'hard'

The newly discovered splice sites are labeled with asterisks 1289

1290 overlaps when only overlapping transcripts are produced from 1291 the same gene pairs. An important novelty of this study is 1292 the discovery that practically each convergent gene produces 1293 rtRNAs crossing the boundaries of the adjacent genes. Two of 1294 the convergent gene pairs (ul3-ul4 and ul30-ul31) form 'hard' 1295 transcriptional overlaps, whereas the other gene pairs form 1296 'soft' overlaps. The 'softly' overlapping convergent transcripts 1297 are likely to be non-polyadenylated, since we were only able to 1298 detect most of them by the random primer-based sequencing 1299 technique. The ul3-ul4 and ul30-31 gene pairs also express 1300 non-polyadenylated rtRNAs that extend beyond their poly(A) 1301 sites. Transcriptional read-troughs were detected between each 1302 convergent gene pair in most cases from both directions, except 1303 in the UL43-44-45/UL48-47-46 cluster (Figure 6 and Table 6). 1304 Another important novelty of this study is the discovery of 1305 very long TSS variants of divergent transcripts, the 5'-UTRs 1306 of which entirely overlap the partner gene. We detected very 1307 long transcripts which overlap the following divergent gene 1308 clusters: ul4-5/ul6-7, ul4-5/ul6-7, ul4-5/ul6-7, ul4-5/ul6-7, 1309 ul9-8/ul10, ul9-8/ul10, ul14-13-12-11/ul15, ul17/ul15e2, ul20-1310 19-18/ul21, ul20-19-18/ul21, ulL23-22/ul24-25-26, ul29/OriL/ 1311

ul30, ul29/OriL/ul30, ul32-31/ul33-34-35, ul37/ul38-39-40, 1312 ul41-ul42, ul49.5.49/ul50, ul51/ul52-53-54, us2/US3, us2/us3, 1313 us2/us3. Altogether, our results show that practically every 1314 nucleotide of the double-stranded HSV-1 DNA is transcribed. 1315

Kinetics of HSV-1 Transcripts

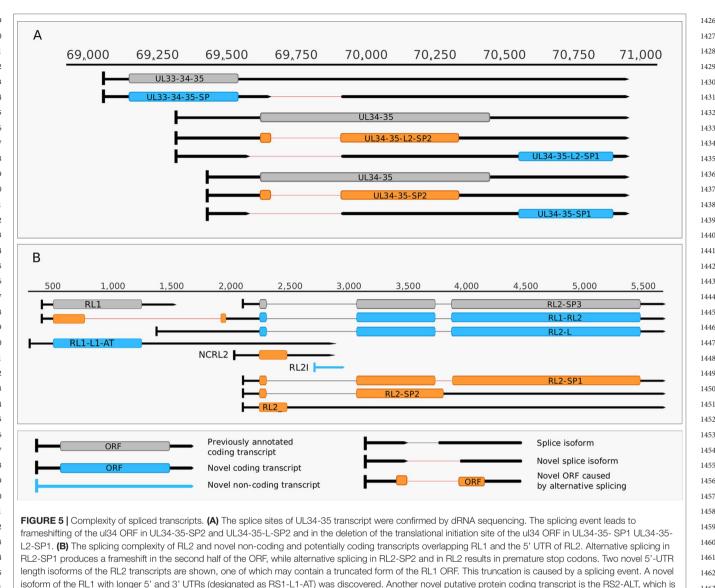

1318 Cultured Vero cells were incubated with HSV-1 for 1, 2, 4, 1319 6, 8, 10, 12, or 24 h. Altogether, we obtained 1,028,840 viral 1320 reads in the kinetic part of the study (Supplementary Table 1). 1321 The distribution of TSSs and TESs along the HSV-1 genome 1322 is illustrated in Figure 7 (see in detail in Supplementary 1323 Figure 2) and Figure 8. The dynamics of various transcript 1324 categories is exemplified in Figure 9, including tmRNAs 1325 (panel A), TSS isoforms (panel B), TES isoforms (panel C), 1326 splice variants (panel D), and polycistronic RNAs (panel E). 1327 Many mono- and polycistronic RNAs and transcript isoforms 1328 are differentially expressed throughout the replication 1329 cycle of the virus. The cumulative abundance of transcript 1330 isoforms in distinct period of HSV infection is depicted in 1331 Supplementary Figure 3. 1332

DISCUSSION

In the last couple of years, LRS approaches revealed that 1336 the viral transcriptome is substantially more complex than 1337 previously thought (Boldogkői et al., 2019b). In this study, 2 1338 sequencing platforms (PacBio Sequel and ONT MinION) and 8 1339 library preparation methods were applied for the investigation 1340 of the HSV-1 lytic transcriptome, including both poly(A)+ 1341 and $poly(A)^{-}$ RNAs. This research yielded a number of novel 1342 transcripts and transcript isoforms. We identified novel tmRNAs 1343 embedded into larger host viral genes. All of these short novel 1344 transcripts contain in-frame ORFs, but it does not necessarily 1345 mean that this coding potency is realized in translation. Indeed, 1346 most of the putative tmRNAs are expressed in low abundance 1347 (these were not accepted as transcripts), which raises doubts as 1348 to whether they code for proteins. These transcripts might have 1349 a regulatory role in certain step(s) of gene expression, but we 1350 cannot exclude that they represent mere transcriptional noise. 1351

This study also identified a large number of transcript length 1352 isoforms varying in their TSSs or TESs. In certain genes, we 1353 obtained very high number of TSS isoforms, therefore we did 1354 not name them individually. Many of these length variants 1355 are expressed in low abundance. It is unknown whether these 1356 transcripts have distinct roles, or their function is exactly the 1357 same as the high-abundance variants. It is possible that increasing 1358 coverage further would reveal that transcripts are initiated from 1359 a promoter at each nucleotide within a certain stretch of DNA 1360 with varying probabilities. In the human cytomegalovirus and 1361 HSV it has been shown that the longer TSS variants may contain 1362 uORFs which may have a role in the translational regulation of 1363 downstream ORFs, and shorter TSSs, on the other hand, often 1364 contain N-terminally truncated ORFs (Stern-Ginossar et al., 1365 2012; Balázs et al., 2017a; Whisnant et al., 2019). 1366

In this work, we also detected novel splice sites and splice 1367 isoforms. We applied very strict criteria for the identification 1368

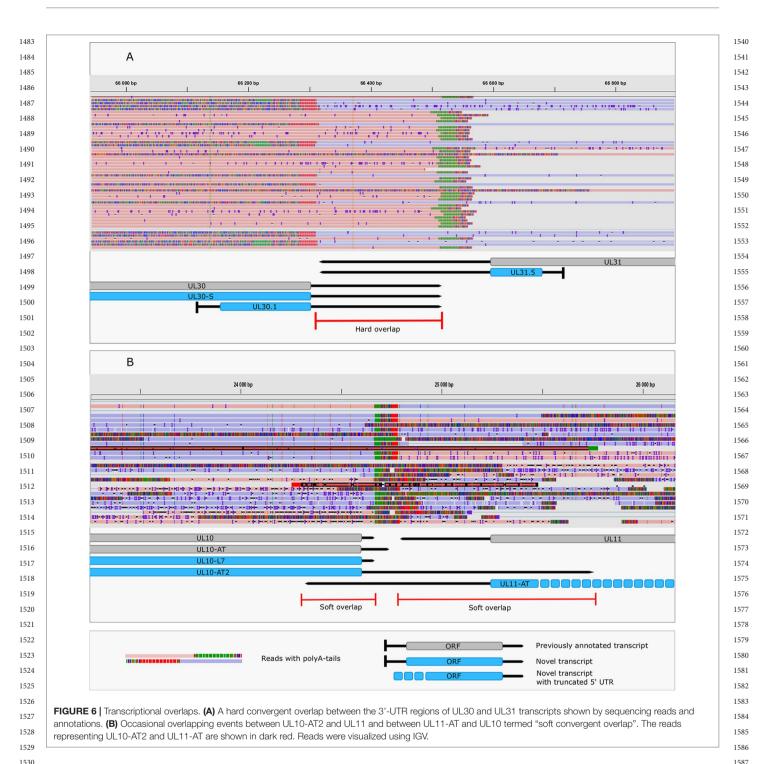

of introns, therefore, many low-abundance introns have been eliminated. Indeed, after the submission of our manuscript, Tang et al. (2019) have reported the existence of several hundreds of splice sites in HSV-1. Further studies have to decide whether these putative introns are artifacts or they really exist.

Here, we also report the identification of several multigenic RNA molecules including polycistronic and complex transcripts. The existence of cxRNAs, expressed from convergent gene pairs, indicates that transcription does not stop at gene boundaries but occasionally continues across genes standing in opposite directions of one another. The cxRNAs are typically expressed in low amount: however, their abundance is difficult to determine precisely because the amount of long transcripts is significantly underestimated by LRS techniques.

We have also detected pervasive antisense transcript expression throughout the entire viral genome especially

with the random primer-based sequencing method. Novel antisense RNAs are typically transcriptional read-through products specified by the promoter of neighboring convergent genes. These normally low-abundance, non-polyadenylated transcription reads contain varying 3'ends. The reason of this phenomenon is the use random nucleotide primers for the RT. The HSV-1 genome also expresses antisense RNAs controlled by their own promoters. For example, we identified a very long 5'-UTR isoform of LAT-0.7 transcript. The LAT RNAs have been shown to play a role in latency (Nicoll et al., 2016). LAT has also been shown to be a source of miRNAs (Lieberman, 2016). Further studies are needed to establish the potential function of LAT expression during the lytic cycle. We also detected novel divergent transcriptional overlaps: in two cases these transcripts appear to be initiated from the 3'-ends of the adjacent genes.

co-terminal with RS1-L1-AT.

In another article, we proposed a potential function for the complex overlapping meshwork formed by transcriptional read-throughs, divergent overlaps, antisense RNAs, as well as polygenic transcripts. We suggest the existence of a novel regulatory layer based on genome-wide interactions between closely located genes through the collision of and competition between their transcriptional machineries (Boldogkői et al., 2019c). Moreover, we could also identify 2 novel replication-associated transcripts—OriL RNA-1 and OriS RNA-3—overlapping OriL and OriS, respectively. Both raRNAs are long TSS isoforms produced from the neighboring genes, *us1* for OriS, and *ul30* for OriL. Similar transcripts have also been recently described in other alphaherpesviruses (Moldován et al., 2017b; Boldogkői et al., 2018; Prazsák et al., 2018). Intriguingly, since the replication origin is located at different genomic regions of herpesviruses, the sequences

AST-3-UL49.5 rtRNA	102,801	103,952

These rtRNAs are probably non-polyadenylated because most of them were detected by random-primed sequencing alone. The genomic locations indicate the mapping of the transcription reads and not the transcript termini. "tt" stands for "read-through", "c"

1625 for "complex".

of raRNAs are non-homologous. The function of these transcripts may be the regulation of the initiation of replication fork as in bacterial plasmids (Tomizawa et al., 1981; Masukata and Tomizawa, 1986), or the regulation of replication orientation through a collision-based mechanism, as suggested earlier (Tombácz et al., 2015; Boldogkői et al., 2019a). In the latter case, raRNAs are mere byproducts of a regulatory mechanism, but it does not exclude the possibility that these transcripts have their own functions, which are at least partly different from those of shorter isoforms.

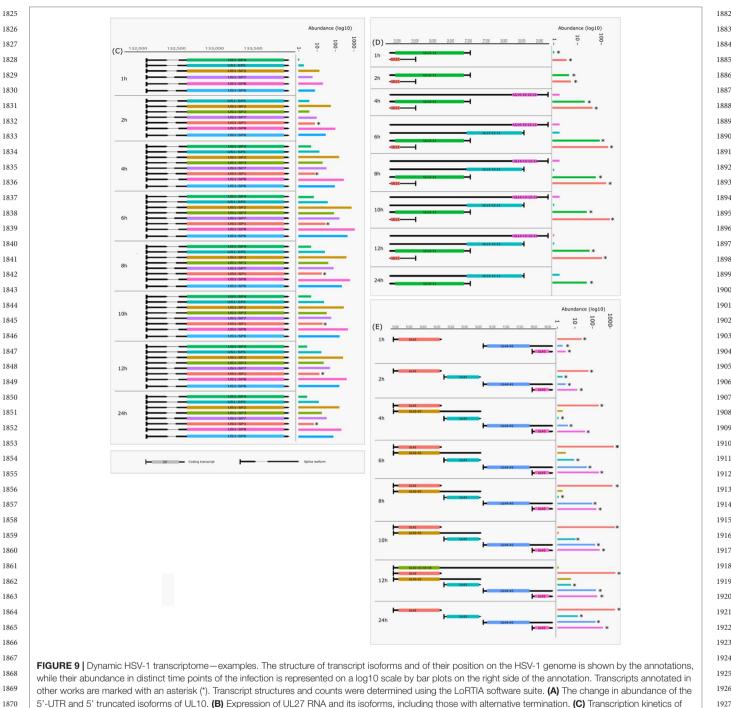

The analysis of the HSV-1 dynamic transcriptome has revealed 1663 a temporally differential expression of transcript isoforms, which suggests a function of these forms of diversity. 1664

The prototypic organization of herpesvirus transcripts with respect to the location of genes is as follows (in the case of adjacent genes): abcd, bcd, cd, and d. However, there are some exceptions to this rule, e.g. the ul41-43 and ul51-49 regions. Both the regular and the irregular gene clusters exhibit time course differences in their location in mono- and various polycistronic RNAs. Genes are also transcribed in various combinations on RNA molecules but the expression of most genes follows the prototypic organization. All in all, this study identified several novel RNA molecules, and transcript isoforms. Further studies have to be carried out to ascertain the function of these transcripts. The question might be raised as to whether the lowabundance transcripts have any function at all, or whether they are the product of transcriptional noise. These transcripts may also be the by-products of a genome-wide regulatory mechanism discussed above, or they may also be functional.

FIGURE 7 | Genome-wide kinetics of the TSSs of HSV-1. The TSSs were determined using the LoRTIA software suite in each sample. Blue dashes represent TSSs on the forward strand, while red dashes represent TSSs on the reverse strand. Black dashes represent previously known TSSs, whereas grey lines starting from the TSS and spanning to the bottom of the figure show the locations of known TSSs in every sample. Orange rectangles represent the ORFs. A higher resolution illustration is presented in **Supplementary Figure 2**.

5'-UTR and 5' truncated isoforms of UL10. (**B**) Expression of UL27 RNA and its isoforms, including those with alternative termination. (**C**) Transcription kinetics of the US1 splice variants. (**D**) The change in abundance of polycistronic and monocistronic transcripts in the coterminal transcript at the UL11-UL14 region. (**E**) Transcription kinetics abundance of polycistronic and monocistronic transcripts in the UL42-UL45 region. Some of these transcripts are coterminal, while others have alternative terminations.

The PacBio RSII sequencing files and data files have been uploaded to the NCBI GEO repository and can be found with GenBank accession number GSE97785. The alignment files from MinION pooled samples, individual time points and Sequel sequencing have been deposited to the European Nucleotide Archive (ENA) under accession number PRJEB25433. Additional data from other sources utilized in this work for validation of rare transcripts and isoforms are available at the ENA with the study accession code PRJEB27861 (MinION dRNA-seq).

DATA AVAILABILITY

The datasets generated for this study can be found in European Nucleotide Archive, PRJEB25433.

AUTHOR CONTRIBUTIONS

DT designed the experiments, prepared the PacBio and ONT sequencing libraries, performed the PacBio RSII, Sequel and ONT MinION sequencing, analyzed the data, and drafted the manuscript. NM analyzed the dynamic transcriptome data and drafted the manuscript. ZBa adapted the LoRTIA pipeline for the analysis. GG analyzed the PacBio and ONT dataset and maintained the cell cultures. ZC isolated RNAs, generated cDNAs, prepared ONT libraries, and performed ONT MinION sequencing. MB analyzed the PacBio data and made manuscript revisions. MS conceived and designed the experiments. ZBo conceived and designed the experiments, supervised the study, analyzed the data, and wrote the final manuscript. All authors have read and approved the final version of the manuscript.

FUNDING

⁴ This study was supported by OTKA K 128247 to ZBo and OTKA
⁵ FK 128252 to DT. DT was also supported by the Bolyai János
⁶ Scholarship of the Hungarian Academy of Sciences and by the
⁷ Eötvös Scholarship of the Hungarian State. The project was
⁸ also supported by the NIH Centers of Excellence in Genomic
⁹ Science (CEGS) Center for Personal Dynamic Regulomes
⁹ [5P50HG00773502] to MS.

ACKNOWLEDGMENTS

We would like to thank Marianna Ábrahám (University of Szeged) for her technical assistance. This study was supported by OTKA K 128247 to ZBo and OTKA FK 128252 to DT. DT was also supported by the Bolyai János Scholarship of the

SUPPLEMENTARY MATERIAL

The Supplementary Material for this article can be found online at: https://www.frontiersin.org/articles/10.3389/fgene.2019.00834/ full#supplementary-material

SUPPLEMENTARY FIGURE 1 | Workflow of the data analysis.

SUPPLEMENTARY FIGURE 2 High resolution TSS kinetics. TSSs and TESs were determined using the LoRTIA software suite in each sample. Blue dashes represent TSSs on the forward strand, while red dashes represent TSSs on the reverse strand. Orange rectangles represent the ORFs.

SUPPLEMENTARY FIGURE 3 | The cumulative abundance of transcript isoforms. Transcript isoforms were annotated and counted in separate stages of the viral infection using the LoRTIA software suite. The names of isoforms annotated in previous works by other methods are in red, whereas the isoforms detected by long-read sequencing are in black.

SUPPLEMENTARY TABLE 1 | Reads' statistics.

SUPPLEMENTARY TABLE 2 | TSSs, TESs and introns.

SUPPLEMENTARY TABLE 3 | (A) Genome coordinates and abundance of transcripts identified by software. TSSs with bold letters were detected in at least 3 independent samples. **(B)** Spliced transcripts with genome coordinates and intron abundances. Abbreviations: HA: highly abundant, A, abundant; LA, low abundance.

SUPPLEMENTARY TABLE 4 Novel 5'-truncated transcripts with putative coding potential. This table summarizes novel and the previously published embedded mRNAs, as well as their genomic positions. Asterisks indicate transcripts that were also detected in our earlier study (Tombácz et al., 2017b).

SUPPLEMENTARY TABLE 5 NcRNA_codepot table. The table enlists the transcript start and end positions, the ORF composition, excluding introns for spliced ORFs, the orientation of the ORFs, the size of the ORF and the amino acid sequence of the ORF. Homology of these ORFs was analyzed by aligning them to Non-redundant protein database using the BLASTp suite. Hits with the highest E-score were included in the table.
