### S1. Complexation between $\text{Al}(\text{OH})_4^-$ and $\text{Hpgl}^-$ ions

*Potentiometric titrations.* During the first series (black curves) the  $[\text{Hpgl}^-]_{\text{T}}$  concentration was varied between 0.200 – 0.400 M and the  $[\text{Al}(\text{OH})_4^-]_{\text{T}}$  concentration was set to 0.200 M. In the strongly alkaline regime ( $\text{pH}_c \approx 13.5$ ) increasing the ligand concentration causes a shift towards higher  $E_{\text{cell}}$  values of the corresponding curves, implying that the value of  $E_{\text{cell}}$  is governed by  $[\text{Hpgl}^-]_{\text{T}}$ . Although the magnitude of change in the initial values could be entirely attributed to the extent of deprotonation, the observed difference is two times bigger of that experienced during the deprotonation of ligand (*Fig. S1*), indicating complex formation. Moreover, the lack of complexation would result the precipitation of gibbsite ( $\text{Al}(\text{OH})_3(\text{s})$ ) or other various aluminum-hydroxides.

**Figure S2** Measured  $\text{pH}_c$  values ( $= \log([\text{H}^+]/c^\ominus)$ ) as a function of added titrant volume in solutions consisting of heptagluconate and HCl. The initial compositions are shown on the legend. Symbols represent the measured data, lines were fitted on the basis of the speciation model discussed in the text and provided in *Table 1*. Experimental conditions:  $T = (25 \pm 0.1)^\circ\text{C}$  and  $I = 4 \text{ M}$  (NaCl)

**Figure S3** Measured  $\text{pH}_c$  values ( $= \log([\text{H}^+]/c^\ominus)$ ) as a function of added titrant volume in solutions consisting of heptagluconate and NaOH. The initial compositions are shown on the legend. Symbols represent the measured data, lines were fitted on the basis of the speciation model discussed in the text and provided in *Table 1*. Experimental conditions:  $T = (25 \pm 0.1)^\circ\text{C}$  and  $I = 4 \text{ M}$  (NaCl)

*Polarimetry.* First the molar rotation power of the individual components was determined. The prepared solutions and the corresponding degrees of rotation were as follows:

$$\begin{aligned} [\text{Hpgl}^-]_{\text{T}} = 0.175 \text{ M} / [\text{OH}^-]_{\text{T}} = 0.200 \text{ M} & \quad \theta = 0.4^\circ \\ [\text{Al}(\text{OH})_4^-]_{\text{T}} = 0.250 \text{ M} / [\text{OH}^-]_{\text{T}} = 0.200 \text{ M} & \quad \theta = 0.0^\circ \\ [\text{OH}^-]_{\text{T}} = 0.200 \text{ M} & \quad \theta = 0.0^\circ \end{aligned}$$

The first solution contained heptagluconate dissolved in sodium hydroxide to avoid lactonization. This way the ligand is mainly in the form of  $\text{Hpgl}^-$  and the extent of deprotonation, referring to one of the alcoholic OH groups, was  $\sim 37\%$ .

The other two solutions were control measurements with components not contributing directly to the rotation power. This approach ensured, that the observed change in the degrees of rotation was exclusively caused by the metal–ligand interaction.

Keeping the specific rotation of  $\text{Hpgl}^-$  constant, the evaluation of polarimetric data with the software PSEQUAD were carried out. First the model obtained by potentiometry was fitted, considering the possible species forming in the highly alkaline region ( $\text{pH} \sim 13$ ). Accordingly, fitting  $\text{Al}(\text{OH})_4\text{Hpgl}^{2-}$ ,  $\text{Al}(\text{OH})_5\text{Hpgl}^{3-}$  and  $\text{Al}(\text{OH})_5\text{Hpgl}_2^{4-}$  resulted  $\text{FP} = 0.34^\circ$ . The systematic deviation between the calculated and measured optical rotation gradually increased with higher  $[\text{Hpgl}^-]_{\text{T}}$ , implying the existence of additional (polynuclear) species. Supposing the formation of  $\text{Al}_3(\text{OH})_{13}\text{Hpgl}_6^{6-}$ , yielded  $\text{FP} = 0.12^\circ$  and  $\log \beta_{32-1} = -6.56(36)$ . The inclusion of this trinuclear species significantly reduced the deviation depicted on *Fig. 3*, as well as the fitting parameter, which is thus comparable with the range of error. However the relatively large standard deviation maybe caused by the high correlation of the included species.

**Table S1** Specific rotation of the individual species forming in the  $\text{Al}(\text{OH})_4^- - \text{Hpgl}^-$  system. Experimental conditions:  $T = (25 \pm 2)^\circ\text{C}$  and  $I = 4 \text{ M}$  (NaCl). Total concentrations:  $[\text{Al}(\text{OH})_4^-]_{\text{T}} = 0 - 0.800 \text{ M}$  and  $[\text{Hpgl}^-]_{\text{T}} = 0.100 - 0.400 \text{ M}$ .

Species	$[\alpha]_{\text{D}}$ $^\circ \cdot \text{dm}^{-1} \cdot \text{cm}^3 \cdot \text{g}^{-1}$
$\text{HpglH}_-1^{2-}$	5.80
$\text{Al}(\text{OH})_5\text{Hpgl}^{3-}$	60.69
$\text{Al}(\text{OH})_4\text{Hpgl}^{2-}$	27.09
$\text{Al}(\text{OH})_5\text{Hpgl}_2^{4-}$	15.08
$\text{Al}_3(\text{OH})_{13}\text{Hpgl}_6^{6-}$	45.40
$\text{Al}_4(\text{OH})_{15}\text{Hpgl}_3^{6-}$	76.78

**Figure S4** Speciation diagram as a function of  $[\text{Al}(\text{OH})_4^-]_{\text{T}}$  in regard to  $\text{Hpgl}^-$ . The calculations were on the basis of stability constants provided in *Table 1.*, corresponding to  $T = (25 \pm 0.1)^\circ\text{C}$  and  $I = 4 \text{ M}$  (NaCl). Total concentrations:  $[\text{Al}(\text{OH})_4^-]_{\text{T}} = 0 - 0.800 \text{ M}$  and  $[\text{Hpgl}^-]_{\text{T}} = 0.100 \text{ M}$ .

**Figure S5** Speciation diagram as a function of  $[\text{Al}(\text{OH})_4^-]_T$  in regard to  $\text{Hpgl}^-$ . The calculations were on the basis of stability constants provided in Table 1., corresponding to  $T = (25 \pm 0.1)^\circ\text{C}$  and  $I = 4 \text{ M}$  (NaCl). Total concentrations:  $[\text{Al}(\text{OH})_4^-]_T = 0 - 0.800 \text{ M}$  and  $[\text{Hpgl}^-]_T = 0.200 \text{ M}$ .

**Figure S6** Speciation diagram as a function of  $[\text{Al}(\text{OH})_4^-]_T$  in regard to  $\text{Hpgl}^-$ . The calculations were on the basis of stability constants provided in Table 1., corresponding to  $T = (25 \pm 0.1)^\circ\text{C}$  and  $I = 4 \text{ M}$  (NaCl). Total concentrations:  $[\text{Al}(\text{OH})_4^-]_T = 0 - 0.800 \text{ M}$  and  $[\text{Hpgl}^-]_T = 0.400 \text{ M}$ .

**Figure S7** Speciation diagram as a function of  $\text{pH}_c$  ( $= \log ([\text{H}^+]/c^\circ)$ ) with regard to Al(III). The calculations were performed using the stability constants provided in Table 1, corresponding to  $T = 25^\circ\text{C}$  and  $I = 4\text{ M}$  (NaCl). Total concentrations:  $[\text{Al}(\text{OH})_4^-]_{\text{T}} = 0.002\text{ M}$ ,  $[\text{Hpgl}^-]_{\text{T}} = 0.004\text{ M}$ .

## S2. Freezing Point Depression measurements

Additional experimental data were collected to reinforce the calculated speciation in our target solutions. This simple method proved to be handy to support the results obtained by other experimental methods.[1] The Freezing point depression, being a colligative property, in relatively dilute solutions is proportional to the total concentration of the ions:

$$\Delta T_{f,\text{theo}} = K_f \cdot \sum_{i=1}^n [X_i]_{\text{T}}, \quad (\text{S1})$$

where  $K_f$  is the cryoscopic constant for water (which is taken  $1.86^\circ\text{C} \cdot \text{M}^{-1}$ , and the term  $\sum_{i=1}^n [X_i]_{\text{T}}$  refers to the total concentration of discrete ions in the solution. If the number of solute particles decreases, *e.g.* complex formation takes place, the freezing point depression also decreases. The measured value corresponds to the sum of equilibrium concentrations:

$$\Delta T_{f,\text{meas}} = K_f \cdot \sum_{i=1}^n [X_i]. \quad (\text{S2})$$

In order to quantify the difference between the theoretical (*i.e.* assuming full dissociation) and the observed values, the following equation could be used:

$$\Delta \Delta T_f = T_{f,\text{theo}} - T_{f,\text{meas}} = K_f \cdot \sum_{i=1}^n ([X_i]_{\text{T}} - [X_i]), \quad (\text{S3})$$

where  $\Delta \Delta T_f$  refers to the extent of particle decrease, therefore to the extent of association. This parameter and the measured FPD values for solutions with various  $\text{NaAl}(\text{OH})_4$ ,  $\text{NaHpgl}$ ,  $\text{NaOH}$  and  $\text{NaCl}$  are presented in Table S1. Examining the first seven solutions, which are exclusively strong electrolytes, the value  $\Delta T_{f,\text{meas}}$  agrees well with those calculated assuming the full dissociation of the particles ( $\Delta T_{f,\text{theo}}$ ). In these solutions the  $\Delta \Delta T_f$  value refers to the uncertainty of the method and can be taken as  $0.14^\circ\text{C}$  considering the range of experiments. In solutions containing both  $\text{Al}(\text{OH})_4^-$ ,  $\text{Hpgl}^-$  and  $\text{OH}^-$ , starting from composition No. 8, the parameter  $\Delta \Delta T_f$  is significantly higher (at least two times), than the uncertainty of the method. Since this parameter indicates the magnitude of association, its increment may be attributed to complex formation. Regarding the first  $\text{Al}(\text{OH})_4^-$ -dependent solution series (No. 9.– 13.), the value of  $\Delta \Delta T_f$  increases until 3:2 metal:ligand ration, where the speciation curve of  $\text{Al}_3(\text{OH})_{13}\text{Hpgl}_6^{2-}$  reaches

its saturation point (Fig. S2), hence the change of  $\Delta \Delta T_f$  could be mainly credited to the formation of  $\text{Al}_3(\text{OH})_{13}\text{Hpgl}_6^{2-}$  species.

In order to attest the performance of the suggested model, the number of particles in the solutions, consequently the expected freezing point depression values ( $\Delta T_{f,\text{calc}}$  presented in Table S1), were calculated on the basis of

compositions and stability constants presented in *Table 1*, with the aid of PSEQUAD software. Although the ionic strength and the temperature of the solutions, where the stability constants were obtained at, were rather different than that of during the FPD experiments (which comes inherently from the nature of the applied method), the observed and predicted values agree reasonably well with the observed ones. Therefore these calculations further confirm the validity of the obtained speciation model.

**Table S2** Freezing point depression measurements for the system containing various amounts of NaAl(OH)<sub>4</sub>, NaHpgl, NaOH or NaCl.  $\Delta\Delta T_f$  refers to the difference between the theoretical ( $\Delta T_{f,theo}$ , calculated by assuming complete dissociation of each compound) and measured ( $\Delta T_{f,meas}$ ) FPD. The term  $\Delta\Delta T_f$  is the extent of particle decrease. The calculated FPD values are listed in column  $\Delta T_{f,calc}$ .

#	[NaAl(OH) <sub>4</sub> ] <sub>T</sub> / M	[NaHpgl] <sub>T</sub> / M	[NaOH] <sub>T</sub> / M	[NaCl] <sub>T</sub> / M	$\Delta T_{f,theo}$ / °C	$\Delta T_{f,meas}$ / °C	$\Delta\Delta T_f$ / °C	$\Delta T_{f,calc}$ / °C
