Abstract

Kisspeptins are G protein-coupled receptor ligands originally identified as human metastasis suppressor gene products that have the ability to suppress melanoma and breast cancer metastasis and recently found to have an important role in initiating secretion of gonadotropin-releasing hormone (GnRH) at puberty. In the brain the gene is transcribed within the hippocampal dentate gyrus. Kisspeptin-13 is one of endogenous isoforms that consists of 13 amino acids. Antidepressive-like effects of kisspeptin-13 was studied and the involvement of the adrenergic, serotonergic, cholinergic, dopaminergic or gabaergic receptors in its antidepressant-like effect was investigated in modified forced swimming test (FST) in mice. Mice were pretreated with a non-selective α-adrenergic receptor antagonist phenoxybenzamine, an α1/α2β-adrenergic receptor antagonist, prazosin, an α2-adrenergic receptor antagonist, yohimbine, a β-adrenergic receptor antagonist, propranolol, a mixed 5-HT1/5-HT2 serotonergic receptor antagonist, methysergide, a non-selective 5-HT2 serotonergic receptor antagonist, cyproheptadine, nonselective muscarinic acetylcholine...
receptor antagonist, atropine, D2,D3,D4 dopamine receptor antagonist, haloperidol or γ-aminobutyric acid subunit A (GABAA) receptor antagonist, bicucullin.

FST showed that kisspeptin-13 reversed the immobility, climbing and swimming times, suggesting antidepressant-like effects. Phenoxybenzamine, yohimbine and cyproheptadine prevented the effects of kisspeptin-13 on the immobility, climbing and swimming time. Prazosin, propranolol, methysergide, atropine, haloperidol and bicucullin did not change the effects of kisspeptin-13.

The results demonstrated that the antidepressant-like effect of kisspeptin-13 is mediated, at least in part, by an interaction of the α2-adrenergic and 5-HT2 serotonergic receptors in a modified mouse FST.

**Keywords:** Kisspeptins; Kisspeptin-13; Receptors; Depression

1. Introduction

Kisspeptin, formerly known as metastin was originally identified as a human metastasis suppressor that inhibits metastasis of melanoma and breast cancer [1]. This G protein-coupled receptor ligand was recently found to have an important role in initiating secretion of gonadotropin-releasing hormone (GnRH) at puberty [2]. In central nervous system kisspeptin is transcribed within the hippocampal dentate gyrus. Kisspeptin-13 is one of endogenous isoforms that consists of 13 amino acids [3]. However, little is know about the machanisms and pathways of kisspeptin-13 on brain functions.

Antidepressive-like effects of kisspeptin-13 was studied and the involvement of the adrenergic, serotonergic, cholinergic, dopaminergic or gabanergic receptors in its antidepressant-like effect was investigated in modified forced swimming test (FST) in mice.

Mice were pretreated with a non-selective α-adrenergic receptor antagonist
phenoxybenzamine, an $\alpha_1/\alpha_2$-adrenergic receptor antagonist, prazosin, an $\alpha_2$-adrenergic receptor antagonist, yohimbine, a $\beta$-adrenergic receptor antagonist, propranolol, a mixed 5-HT$\_1$/5-HT$\_2$ serotonergic receptor antagonist, methysergide, a non-selective 5-HT$\_2$ serotonergic receptor antagonist, cyproheptadine, nonselective muscarinic acetylcholine receptor antagonist, atropine, D$_2$,D$_3$,D$_4$ dopamine receptor antagonist, haloperidol or $\gamma$-aminobutyric acid subunit A (GABA$\_A$) receptor antagonist, bicucullin.

2. Materials and methods

2.1. Animals

CFLP male mice were kept and handled during the experiments in accordance with the instructions of the University of Szeged Ethical Committee for the Protection of Animals in Research. Each animal was used in the experiments only once. The animals were housed in cages in a room maintained at constant temperature (25 ± 1 °C) and on a 12-h dark–light cycle (lights on at 06:00–18:00 h) with free access to tap water and standard laboratory food. At least 1 week of recovery from surgery was allowed before the experiments.

2.2. Surgery

The mice were implanted with a cannula introduced into the right lateral brain ventricle in order to allow intracerebroventricular (i.c.v.) administration. The polystyrene cannula was inserted stereotaxically into the ventricle at the coordinates 0.2 mm posterior, 0.2 mm lateral to the bregma, and 2.0 mm deep from the dural surface [4]. The cannula was secured with cianoachrilate (Ferrobond) (Budapest, Hungary). The mice were allowed a minimum of 5 days to recover from surgery before any i.c.v. administration.

2.3. Materials
Kisspeptin-13 was from Bachem (Basel Switzerland). Phenoxybenzamine hydrochloride was obtained from Smith Kline & French (Herts, UK); prazosin hydrochloride from Tocris (; yohimbine hydrochloride from Tocris (Cologne, Germany); propranolol hydrochloride from ICI Ltd. (Macclesfield, UK); methysergide hydrogen maleate from Sandoz (Cologne, Germany); cyproheptadine hydrochloride from Tocris (Bristol, UK); atropine sulphate from EGYS (Budapest, Hungary); haloperidol from G. Richter (Budapest, Hungary); and bicuculline methiodide from Sandoz (Basle, Switzerland).

Kisspeptin-143 was lyophilized in a quantity of 10 µg per ampoule and stored at −20 °C. Immediately before the experiments, kisspeptin-143 was dissolved in sterile pyrogen-free 0.9% saline and administered i.c.v. via the cannula in a volume of 2 µl.

2.4. Forced swimming test

The modified mouse FST was conducted as reported previously [5,6]. The mice were forced to swim individually in a glass cylinder 12 cm in diameter and 30 cm in height, filled with water to a height of 20 cm. The temperature of the water was adjusted to 25 ± 1 C. The water was changed between the individual mice. A 15min pretest session was followed 24 h later by a 5min test session. Phenoxybenzamine (2mg/kg, i.p.), prazosin (62.5 µg/kg, i.p.), yohimbine (5mg/kg, i.p.), propranolol (5mg/kg, i.p.), methysergide (5mg/kg, i.p.), cyproheptadine (3mg/kg, i.p.), atropine (2mg/kg, i.p.), haloperidol (10 µg/kg, i.p.) or bicuculline (2mg/kg, i.p.) were administered 1 h before the test session followed 30min later by kisspeptin (2.0 µg/2 µl, i.c.v.) [7–12]. Physiological saline was used as vehicle control. A time-sampling technique was applied to score the durations of climbing, swimming and immobility. Climbing time was measured when the mouse was participating inactive vertical motion with its forelegs above the water level; swimming time was recorded when the mouse was moving in horizontally on the surface of the water; and immobility time was registered when the
mouse was in a upright position on the surface with its front paws together and making only those movements necessary to keep itself afloat.

2.5. Statistical analysis

The analysis of variance (ANOVA) test was followed by Tukey’s test for multiple comparisons with unequal cell size. Probability values (P) of less than 0.05 were regarded as indicative of significant differences.

3. Results

Kisspeptin-13 (2.0 µg/2 µl)-administered mice exhibited a significantly decreased immobility time \([F(3.35) = 14.98: P < 0.05]\), a significantly increased climbing time \([F (3.35) = 7.75: P < 0.05]\) and a significantly increased swimming time \([F (3.35) = 11.10: P < 0.05]\) (Fig. 1).

Phenoxybenzamine per se (2mg/kg) did not affect the immobility time, climbing time, or swimming time. In kisspeptin-13-treated mice, pretreatment with phenoxybenzamine partially reversed the kisspeptin-13-induced change in the immobility time, and decreased the changes in the climbing and swimming times (Fig. 2).

Prazosin per se (62.5 µg/kg, i.p.) did not affect the immobility time, the climbing time or the swimming time. In kisspeptin-13-treated mice, pretreatment with prazosin did not reverse the kisspeptin-13-induced change in the immobility time, climbing time and the swimming time (data not shown).

Yohimbine per se (5mg/kg, i.p.) did not affect the immobility time, the climbing time, or the swimming time. In kisspeptin-13-treated mice, pretreatment with yohimbine partially reversed the immobility time, climbing time and the swimming time (Fig. 3).

Methysergide per se (5mg/kg, i.p.) did not affect the immobility time, the climbing time or the swimming time. In kisspeptin-13-treated mice, pretreatment with methysergide did not reverse immobility time, the climbing time and the swimming time (data not shown).
Cyproheptadine per se (3mg/kg, i.p.) did not affect the immobility time, the climbing time or the swimming time. In kisspeptin-13-treated mice, pretreatment with cyproheptadine resulted in an increased immobility time and decreased the changes in the climbing and the swimming times (Fig. 4).

Propranolol per se (5mg/kg, i.p.) did not affect the immobility time, the climbing time, or the swimming time. In kisspeptin-13-treated mice time, pretreatment with propranolol did not lead to an increase in the immobility time, and did not affect the climbing time or the swimming time (data not shown).

Atropine per se (2mg/kg, i.p.) did not affect the immobility time, the climbing time, or the swimming time. In kisspeptin-13-treated mice, pretreatment with atropine did not affect the increased immobility time and the decreased climbing and the swimming times (data not shown).

Haloperidol per se (10 µg/kg, i.p.) did not affect the immobility time, the climbing time, or the swimming time. In kisspeptin-13-treated mice, pretreatment with haloperidol did not increase the immobility time nor affect the climbing or the swimming times (data not shown).

Bicuculline per se (2mg/kg, i.p.) did not affect the immobility time, the climbing time or the swimming time. In kisspeptin-13-treated mice pretreatment with bicuculline did not increase the immobility time, or the climbing time, or the swimming time (data not shown).

The above results reveal that the antidepressant-like effect of kisspeptin-13 is mediated, at least in part, by α2-adrenergic receptors and 5-HT2 serotonergic receptors in a modified mouse FST.

4. Discussion

In the central nervous system kisspeptin expressing neurons are located in the anteroventral periventricular nucleus (AVPV), periventricular nucleus (PVN), anterodorsal preoptic nucleus (ADP) and arcuate nuceus (Arc) [13]. In a close relationship to PVN, the neurons of AVPV
and Arc project fibers into the preoptic area rich in GnRH cell bodies. It is now known that kisspeptin stimulates the secretion of GnRH which is sensitive to steroid levels [14]. The previous studies showed that luteinizing hormone releasing hormone (LHRH) antagonist, cetrorelix and growth hormone releasing hormone (GHLH) antagonist kisspeptin-13 have antidepressant-like effects in a modified mice FST, suggesting close relationships between growth hormone regulation and mood disorders alleviation [15,16,17,18].

Kisspeptin-13 is one of endogenous kisspeptin isoforms that consists of 13 amino acids. In this study kisspeptin-13 display antidepressant-like effects in a modified FST. To clarify the mechanism of the antidepressant-like actions of kisspeptin-13, various receptor blockers were applied before kisspeptin-13 administration. The doses of receptor blockers were selected so that blockers per se were ineffective but were able to block the action of a neuropeptide as describe in the previous study [19]. The observation with receptor blockers indicates that the action of kisspeptin-13 is mediated by certain receptors. The results indicated a non-selective $\alpha$-adrenergic receptor antagonist, phenoxybenzamine, an $\alpha_2$-adrenergic receptor antagonist, yohimbine and a non-selective 5-HT$_2$ serotonergic receptor antagonist, cyproheptadine prevented the effects of kisspeptin-13 on the immobility, climbing and swimming time. an $\alpha_1/\alpha_2\beta$-adrenergic receptor antagonist, prazosin, a $\beta$-adrenergic receptor antagonist, propranolol, a mixed 5-HT$_1$/5-HT$_2$ serotonergic receptor antagonist, methysergide, a nonselective muscarinic acetylcholine receptor antagonist, atropine, D$_2$,D$_3$,D$_4$ dopamine receptor antagonist, haloperidol and $\gamma$-aminobutyric acid subunit A (GABA$\alpha$) receptor antagonist, bicucullin did not change the effects of kisspeptin-13.

The results demonstrated that the antidepressant-like effect of kisspeptin-13 is mediated, at least in part, by an interaction of the $\alpha_2$-adrenergic and 5-HT$_2$ serotonergic receptors in a modified mouse FST.
